MODELS 100A & 100C

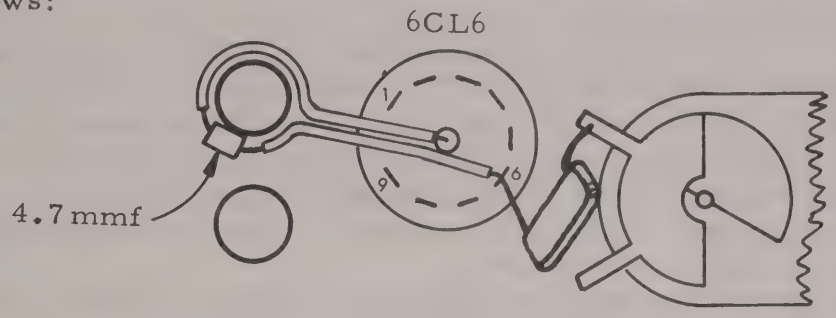
TRANSMITTER GRID DRIVE AND FINAL NEUTRALIZATION

Addendum #4 Model 50
Addendum #6 Model 100
Issued 9/10/62

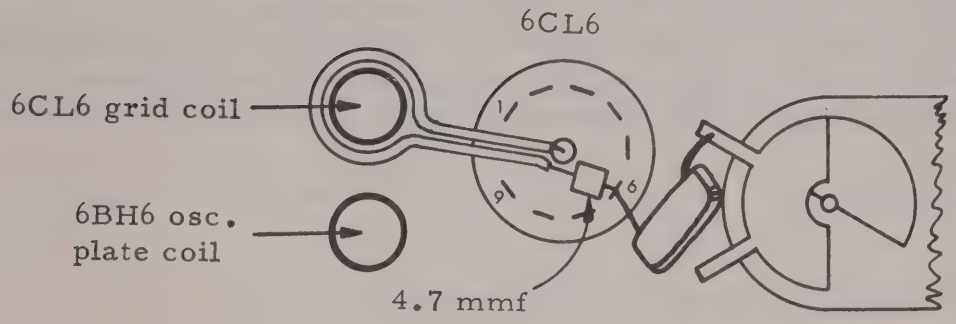
The following changes have been made in late production Model 50A and Model 100A Executive transcievers. It is recommended that these changes be added to all sets where applicable.

1. Neutralization Loop. The 4.7 mmf neutralizing capacitor should be relocated as follows:

OLD



NEW

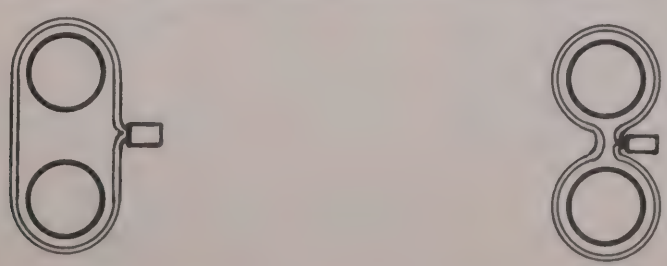


The 4.7 mmf capacitor should Solder directly to pin 6 of the 6CL6 socket with no more than 1/4 inch lead. Splice a piece of insulated wire on the other end of the 4.7 mmf capacitor and run the neutralization loop around the top end of the 6CL6 grid coil just under the top coil lead. This is same position on the coil the loop was previously positioned.

2. Grid Drive Coupling Loop. If the coupling loop has not been installed on sets with double coil coupling; it should be fabricated and installed as follows:

(a) Cut a piece of #24 insulated hook-up wire 3 1/4 inches long. Strip 1/4 inch each end. Twist the two ends together, solder, and insulate the joint.

(b) Form a loop and slip it over the ends of the two coupling coils. Position at the top end of the windings. Squeeze the loop together



between the coils to tighten. Do not twist the ends of the loop with respect to each other-leave as a flat loop as shown.

(3) Tuning Grid Coupling. The double coil coupling is tuned as follows:

(a) Connect the dc probe of a VTVM to the center post of the 6BH6 tube socket. Use the 30volt negative range.
(b) Install a channel 1, 9, and 23 crystal in the transmitter. Set the switch for channel 9. Connect wattmeter to transmitter output and key transmitter.
(c) Tune the 6BH6 plate coil for maximum voltage on VTVM.
(d) Tune the 6CL6 grid coil for maximum voltage on VTVM.
(e) Tune the 6CL6 plate pi-network for maximum power to wattmeter.
(f) Remove channel 9 crystal, key transmitter, and check neutralization for no output. Adjust neutralizing loop if required.
(g) Install channel 9 crystal and repeat steps (c) thru (f) until neutralization is complete.
(h) Now switch the crystals alternately between channel 1 and 23 noting grid drive. Adjust the 6BH6 plate coil for equal drive on 1 and 23. Leave the 6CL6 grid coil peaked for channel 9.
(i) Grid voltage will be 20-25 volts dc channel 9 and 15-20 volts channels 1 and 23. Grid voltage should exceed 13 volts in all cases.
(j) Seal coupling and neutralization loops in position with RTV compound.

(1) Remove case from the Executive

(2) Remove 10455 KC second IF crystal

(3) Connect high impedance DC VTVM probe to grid of second mixer. On late models 100 this will be the top of the 5.6 megohm resistor. On earlier sets this will be the lead from the 2.2 mmf capacitor nearest L8. (figure 3)

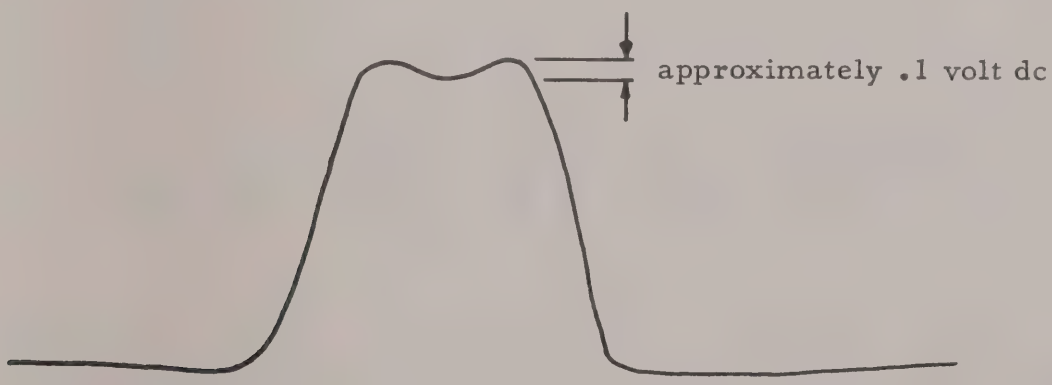
(4) Set the Receive Selector to Tune

(5) Apply a channel 9 signal from the C-12B to the Executive model 100A. Set the C-12B LEVEL control full clockwise. (figure 1)

(6) Slowly tune the receiver thru channel 9 and note the VTVM reading. Off channel the VTVM will read between .5 and 1.0-dc. As you reach the channel the reading will increase (depending upon the amount of signal being applied) to 1.5 volts-dc or more. If the reading goes higher than 2.5 reduce the C-12B signal.

NOTE: No signal will be heard in the speaker since the second mixer crystal has been removed.

Tune slowly across channel 9. The voltage should vary as below



The correct filter setting should have equal peaks plus or minus .1 volt dc from mean value. The valley between peaks should be no greater than .1 volt dc lower than mean.

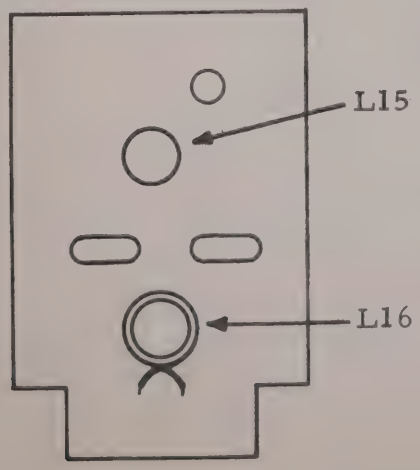


FIG. 4

(7) Where the bandpass is out of tolerance, remove the seal from L15 and L16. L15 will effect the peak heigth and L16 the depth of the valley. These coils are touchy to adjust and only small

FILTER ADJUSTMENT

(a) Check filter bandpass

(b) Set receive crystal trimmer for center of bandpass

(c) Adjust 455 KC IF for peak AVC

(d) Check adjacent channel rejection

The above steps are made as follows:

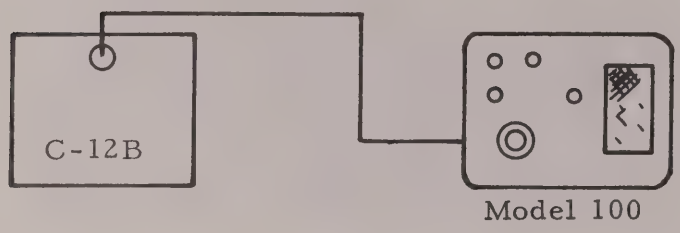

FIG. 1

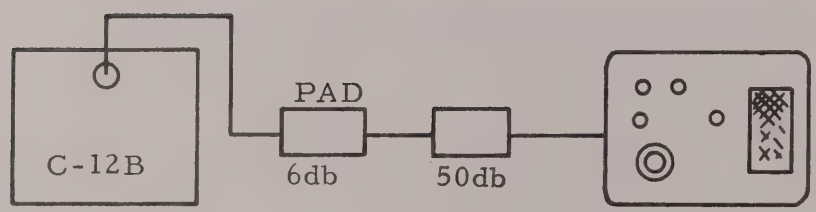

FIG. 2

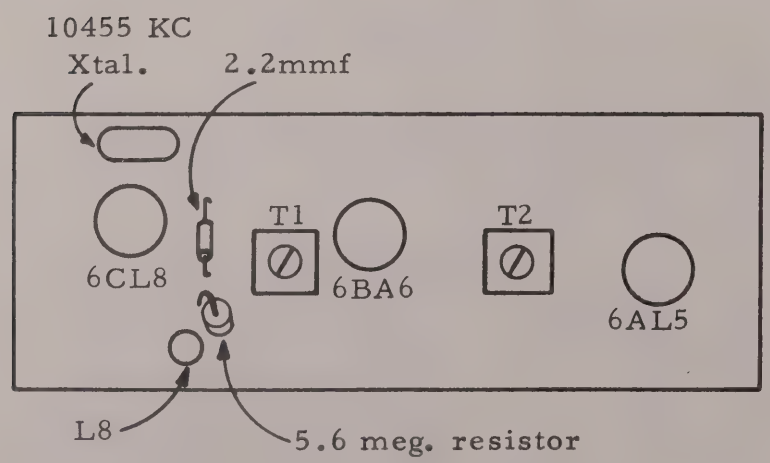

FUG. 3

changes should be made between each tune thru of channel 9. Normal position of the slug in L15 is near the top of the form to 1/8 inch in the form. The slug in L16 extends approximately 1/16 to 1/8 inch out the top of the form. Be sure to seal the slugs after adjustment. Alternately adjust L15 and L16, and then tune across the channel until the desired bandpass is obtained.

(8) Set the RECEIVE SELECTOR to channel 9 crystal receive and rotate its associated trimmer. Note the VTVM reading and leave the trimmer set to a point midway between the bandpass peaks.

(9) Repeat step 8 for each receive crystal using the appropriate channel on the C-12B.

(10) Reinstall the 10455 KC crystal. Install a 6db ∕ 50 db pad between the C-12B and the Executive. (figure 2)

(11) Using channel 9 crystal receive, apply sufficient signal on 9 from the C-12B to give 2 to 3 volts AVC as measured at the accessory socket ACC. Peak the 455 KC IF transformers for maximum AVC.

(12) Set the output of the C-12B for 3 volts AVC channel 9. Check the C-12B output on channels 8 and 10 by tuning them in on the receiver. Plus or minus .25 volts of channel 9 level is satisfactory.

(13) Return to channel 9 crystal receive and switch out 50 db of pad. Apply signal from C-12B on channel 8 and 10. The AVC reading should not exceed the level of channel 9 noted with the 50 db pad in the circuit.

NOTE: There should be at least 6 db of pad in the circuit at all times to prevent variation in load to the C-12B. For accurate rejection check, the above settings must be made with care and no signal leakage can be present.

Addendum #3 Model 50
Addendum #4 Model 100
Issued 6/11/62

Model 50
Effective on units with serial #30200ZD and later.
Model 100
Effective on units with serial #31300ZD and later.

1. In section I, Rear Panel Controls, change last sentence of paragraph titled Power to read as follows.

Five different cord assemblies are used; 115VAC, 6VDC negative ground, 6VDC positive ground, 12VDC negative ground, and 12VDC positive ground. Delete Caution note.

2. In section II under Power Supply Circuit Description change last sentence of first paragraph to read as follows.

On 6 or 12 volt battery operation a transistor oscillator circuit is used to supply the necessary AC, square wave voltage for the primary circuit of the power transformer.

3. Change second sentence of second paragraph under Power Supply Circuit Description to read as follows.

The unit may be operated either from 6 volt positive ground, 6 volt negative ground, 12 volt positive ground, 12 volt negative ground by use of the proper power cord assembly which may be purchased from your dealer.

4. In section III, delete section titled Vibrator Care Is Important.

5. In section IV, change paragraph titled Power Plugs to read as follows.

6VDC	plug	−gnd	Part No. 150-212	Price each	$7.50
6VDC	plug	+gnd	Part No. 150-213	Price each	$7.50
12VDC	plug	−gnd	Part No. 150-214	Price each	$7.50
12VDC	plug	+gnd	Part No. 150-215	Price each	$7.50
115VAC	plug		Part No. 150-174	Price each	$7.50
DC	plug kit		Part No. 150-191	Price each	$3.95
AC	plug kit		Part No. 150-192	Price each	$3.95

6. In section IV, under title Wiring Power Plug For Model 100 change the first sentence to read as follows.

The 3-way power supply may be operated from any one of 5 different power systems; 115VAC; 6VDC positive ground, 6VDC negative ground, 12VDC positive ground, 12 VDC negative ground.

Delete all drawings and pin connections in this section and substitute the following.

115VAC Model 50 & 100
Part # 150-174
115VAC to pins 1 and 4
Jumper pins 2 and 3
Jumper pins 13 and 18

Part # 150-212

ADDENDUM TO MODEL 100 3/21/62

Effective on units with (SD) serial numbers and later.

Change the following component on power supply schematic.

Change R50 from 39 ohm 2W 10%
to 56 ohm 2W 10%

On Transmitter Model 100 Circuit Add Neon Bulb across the Relay Coil TR-1.

Addendum #2
Issued 5-24-62

Receiver Alignment

1. Change paragraph 5 to read as follows.

Turn the Executive unit on and set the Receive Selector to crystal 9 (use 115 VAC for these steps). Key the C12-B for a channel 9 signal and adjust the crystal trimmer in the Executive for maximum AVC or midway between the two "hiss levels" heard when the trimmer is rotated back and forth. (Center carrier)

2. Change paragraph 8 to read as follows.

After the above adjustments have been made, return to coil L7 and rotate the slug 1/4 turn in the direction of minimum inductance.

3. Move section entitled Adjustment of tunable First Oscillator to follow paragraph 8 under Receiver Alignment.

4. Add the following after section entitled Adjustment of Tunable First Oscillator.

Crystal Filter Test

1. To check for proper operation of the crystal filter, connect a C12-B through a 60 db pad to the Executive antenna receptacle.

2. Set the Receive Selector to tune and rotate the tuning dial to the channel 9 mark.

3. Key the C12-B for a channel 9 signal and carefully adjust the Executive tuning dial for maximum AVC or midway between the two "hiss levels" heard as the dial is moved back and forth across the channel 9 position.

4. Increase the C12-B LEVEL control until you obtain an AVC voltage of 9 volts. This is the approximate AVC voltage obtained when a 300 microvolt signal is applied to the Executive.

5. Without changing the C12-B LEVEL control, set the C12-B to channel 8 and tune the Executive for the center of the pass band as in step 3 above. Repeat this procedure for channel 10. In both cases note that the AVC voltage does not vary more than 1.0 volt from that obtained in step 4 above.

6. Repeat step 3 above and leave the Executive tuning dial on channel 9.

7. Key the C12-B for a channel 8 signal and then a channel 10 signal. In both cases the AVC voltage should not change more than 10% of the AVC voltage obtained in step 4 above. Remember the receiver is tuned to channel 9 during this test.

8. If the voltage change is within this limit the filter is functioning properly and will give 50 db adjacent channel rejection.

Addendum #5 Model 100
Issued 12-3-62

11-26-62

Change the following components in the I.F. Unit:

1. Change R14 from 68k ohms 1/2 W 10%
to 56k ohms 1/2 W 10%

2. Change R24 from 68 ohms 1/2 W 10%
to 82 ohms 1/2 W 10%

3. Change C40 from .02 mfd disc capacitor
to .068 mfd tubular capacitor

4. Change C45 from .01 mfd disc capacitor
to .001 mfd disc capacitor

5. Connect a 220 mmfd disc capacitor from the high side of the volume control to the roter of said control.

TABLE OF CONTENTS

Issued 3/21/62

LIST OF ILLUSTRATIONS

SECTION I

GENERAL

The INTERNATIONAL EXECUTIVE, Model 100, is a Citizens Band unit which combines sensitive and super selective, dual conversion superhetrodyne receiver, with a highly stable and efficient, crystal controlled transmitter. The complete transmitter, receiver and power supply are housed in an attractive brown and silver colored cabinet to blend favorably in the home, office, car or truck.

The EXECUTIVE Model 100 receiver is the first commercially available citizen band unit to make use of a high-frequency crystal filter to achieve and permanently guarantee receiver selectivity for the life of the equipment. Use of this filter between the first and second mixers greatly reduces adjacent channel interference and offers a very flat response throughout the band-pass of the filter.

The receiver manually tunes all 23 Class "D" Citizens Band channels. In addition, two receiving crystal sockets are provided in the unit for the selection of any two desired channels. The selection of either crystal controlled channel, or manual tuning is accomplished with a three position switch on the front panel. A squelch circuit is built-in to provide receiver quieting during periods when no signal is being received.

The transmitter oscillator uses fundamental crystals operating at one-half the desired operating frequency. The crystals supplied have a frequency tolerance of .005% when used in the EXECUTIVE. A twelve position crystal switch assembly allows the operator to choose anyone of twelve channels at the flick of the switch.

The EXECUTIVE has been designed with flexibility of installation in mind. It may be used in the home or office with power secured from the AC line. It may also be used in a car, boat, plane or other mobile and portable applications, wherever there is 6 or 12 VDC available. It may be used with a base loaded whip antenna, regular whip, long wire, ground plane, beam and other types of antennas. The attractive case design lends itself to use in the home or office without appearing unsightly or out of place.

Though the unit is very versatile, it is not to be expected that either receiving or transmitting results will be the same in every installation. As in all radio communications and particularly in VHF applications, the type of antenna, its location above ground, the noise present in the area and other factors are bound to affect the results obtained.

SPECIFICATIONS

Receiver:

Tuning Range (Manual tuning)	26.955 to 27.265 mc, (Class "D" Citizens Band, Channels 1 through 23).
Tuning Range (Selector Pos. 2)	Crystal Controlled - Any Channel, 1 through 23.
Tuning Range (Selector Pos. 3)	Crystal Controlled - Any Channel, 1 through 23.
Sensitivity	Usable to .5 microvolts
Selectivity	50 db down at 10 kc better than 60 db down at 20 kc
Image Rejection	Better than 50 db down
Audio Output	2.5 watts into 4-6 ohms
Speaker Impedance	4-6 ohms
Squelch Range	1 to 50,000 microvolts. On-off differential is approximately 1 microvolt, at 5 microvolt input.
Noise Limiter	Automatic, series-gate

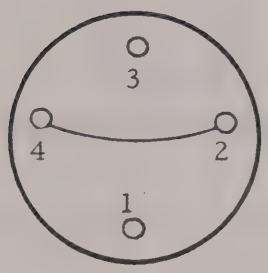
TRANSMITTER

Frequency Stability	±.005% @ 0° to 125° F, when used with INTERNATIONAL high stability fundamental crystals.
RF Power Input	5 watts maximum (FCC rules)
Modulation	Capability - 100%
Crystals Required	Transmitter - INTERNATIONAL "T" (T-9 for Channel 9, etc.), high stability, fundamental type, at one-half the desired frequency. Receiver INTERNATIONAL "R" (R-9 for Channel 9, etc.)

Microphone	High impedance crystals, ceramic or high output dynamic type. (Push-to-talk switch required.)

POWER CONSUMPTION

Transmitting	65 watts (approximate)
Receiving	60 watts (approximate)
Weight	12 pounds (approximate)

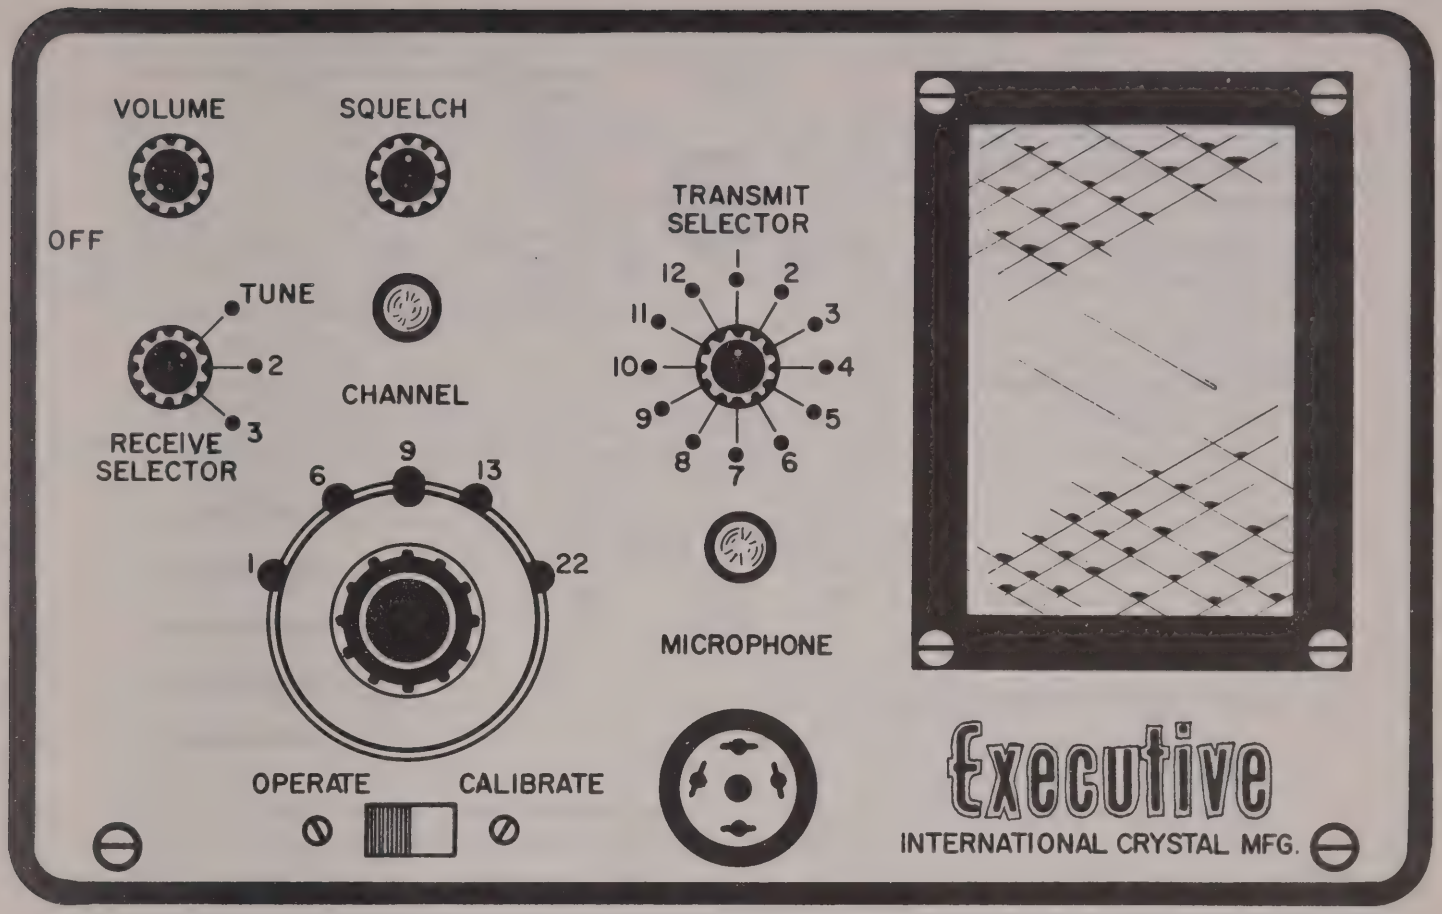


HI-IMPEDANCE MICROPHONE PLUG WIRING

Pin 1 - Hot lead of mike
Pin 2 - Shield of mike cable
Pin 3 - From Switch
Pin 4 - Mike switch
A jumper is placed from pin 2 to pin 4.

NOTE: When pin 4 of the plug is grounded, as it is when the mike switch is closed, the relay in the EXECUTIVE is energized, operating the transmitter section of the unit.

Issued 3/21/62



FRONT PANEL CONTROLS

VOLUME

On-off switch, volume control. To turn receiver on, turn the knob clockwise. Clockwise rotation of the knob also increases the volume level.
Allow the set to warm up for about one minute before you wish to use it.

SQUELCH

This control is used to eliminate background noise when no signal is being received. Upon initial warmup, turn this control fully counter clockwise until a click is heard. The switch in the squelch control is **off** in this position. To operate, turn squelch control on and fully clockwise. Then slowly turn the control counterclockwise until the background noise just disappears. Leave the control set at this point. Do not turn the control too far counterclockwise as this will reduce the receiver performance and weak signals will not be heard.

RECEIVE SELECTOR

Set this control to TUNE unless receiver crystals have been installed in positions #2 and #3, in which case set the switch to the desired crystal position for crystal controlled reception.

TRANSMIT SELECTOR

A channel 9 crystal has been installed at the factory in switch position #2. Place the switch in this position unless you have had other crystals installed, in which case select the channel on which you desire to transmit.

CHANNEL (Tuning)

With the RECEIVE SELECTOR set in TUNE position this control tunes the receiver through the range of all 23 channels. The approximate locations of channels 1, 6, 9, 13 and 22 are indicated on the panel. Other channels fall in between these points.

OPERATE-CALIBRATE (Switch)

During normal operation this switch is left in the OPERATE position. When it is desired to pretune the receiver to a specific Channel (you must have a transmit crystal for this channel installed in the Transmit Selector crystal socket) set the controls as follows:

TRANSMIT SELECTOR to the desired channel.
OPERATE-CALIBRATE switch to Calibrate.
SQUELCH CONTROL full counterclockwise to click **Off.**
RECEIVE SELECTOR to Tune.
Rotate tuning dial until the loudest part of the tone signal is received. Rock the tuning dial back and forth to locate the center of the signal. Leave tuning dial at this point and the receiver is pretuned to transmit channel you have selected.

MICROPHONE (Receptacle)

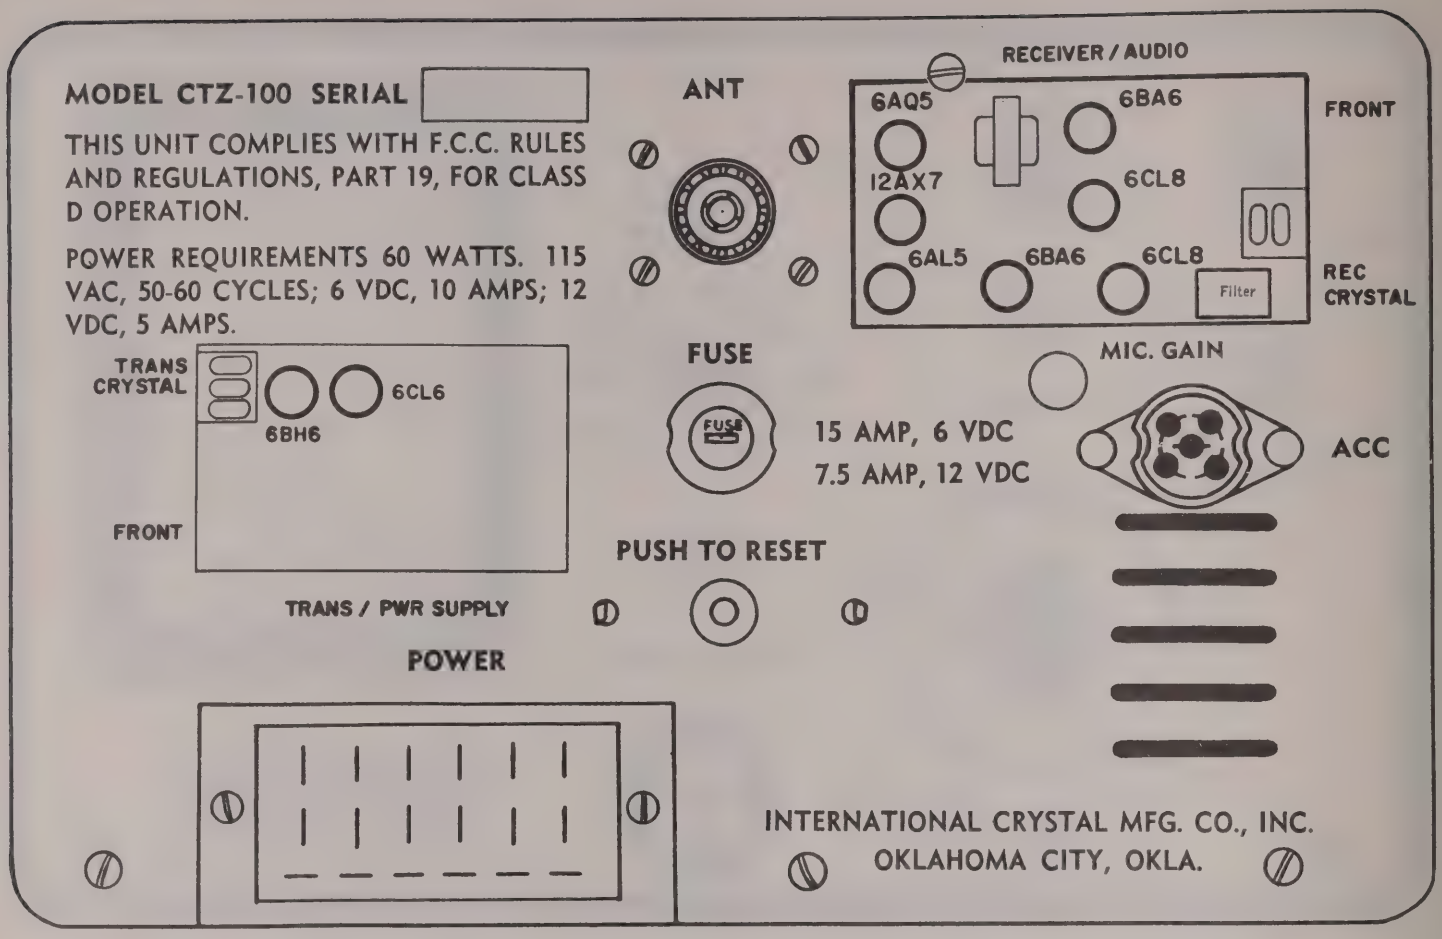
This connector requires a four prong lock-on plug which is furnished with the unit. High impedance crystal or ceramic type microphones may be used with this transceiver.

RECEIVE (Indicator)

This indicator, located directly below the squelch control, functions as an ON-OFF (plate voltage) indicator for the receiver section of the transceiver. When the transceiver is operating in RECEIVE position, the lamp will glow steadily and go out when the transceiver is placed in TRANSMIT position.

TRANSMIT (Indicator)

This indicator functions as an audio level monitor. Depress the microphone keying button and speak directly into microphone. The indicator light will flicker intermittently as you speak in a normal voice level. With indicator operating on voice peaks, modulation will be about 95%. When talking too close to microphone the indicator lamp will glow almost constantly. This can result in overmodulation and cause adjacent channel interference. This indicator will flicker when the transceiver is in RECEIVE position also, showing proper operation of the receiver audio section.



REAR PANEL CONTROLS

ANT (Antenna Receptacle)

This receptacle is used to connect the transceiver line to the transmit-receive relay, TR-1. The receptacle is a standard low-loss, VHF type designed for 50- to 72-ohm coaxial cable.

ACC (Accessory Receptacle)

This connector requires a five prong plug which is furnished with the unit. This plug contains a jumper for internal speaker operation and must be in place for the set to function. An external speaker and Signal Strength ("S") Meter may be connected to this set with this connector.

FUSE

A 15 ampere fuse is installed in the fuseholder and may be changed or replaced, if necessary, by unscrewing the red insert in the center of the holder. If the transceiver is to be operated on 12 volts dc the fuse should be replaced with one having a rating of 7.5 amperes.

MIC. GAIN (Microphone Level)

This control (yellow knob) adjusts microphone amplifier gain. The level has been factory set for close microphone operation. For base station operation, where the operator desires to talk several inches back from the microphone, this control may be turned clockwise until the red Transmit Indicator lamp flashes on voice peaks.
CAUTION: Excessive gain will cause overmodulation.

PUSH TO RESET

This is a thermal cut-out. It protects the unit when it is being operated on 115 volts ac. If overload causes it to cut out, it can be reset by pressing in on the plunger and holding it in for about two seconds.

POWER

An 18-contact plug is used as a power connector. This allows various input voltages to be used without requiring changes within the unit. All necessary connection changes are made on the external plug. Three different power cord assemblies are used, one for each input voltage. CAUTION: The 115 VAC Power Cord for the Executive Model 100 and Model 50 are wired differently. Use only the proper power cord for the Model 100—Part Number 150-174.

SECTION II

RECEIVER CIRCUIT DESCRIPTION

The receiver section of this transceiver is a double conversion unit employing the superheterodyne principle of frequency conversion. The first converter is composed of three basic sections; an rf amplifier, mixer, and oscillator which is either tunable or crystal controlled.

A received signal from the antenna is coupled to the control grid of the rf amplifier through a double tuned circuit consisting of coils L1 and L2, their respective shunting capacitors, and coupling capacitor C3. This double tuned circuit aids greatly in the elimination of unwanted signals outside the passband to which it has been tuned. The gain of the rf amplifier is controlled automatically by the receiver's AVC system coupled to the control grid of V1 through a 1 megohm resistor.

After reaching the control grid of V1 (6BA6) the signal is amplified and coupled to the control gird of the mixer, V2A (triode section of 6CL8A). Here the signal is heterodyned with a signal in the 17 mc region coupled from the oscillator, V2B (tetrode section of 6CL8A). A difference frequency signal at 10 mc is selected by coil L4 in the plate circuit of the mixer, V2A and coupled to the grid of the second mixer in the I. F. strip through the 10 mc crystal amplifier-filter assembly.

The oscillator is a conventional Colpitts circuit which may be either crystal controlled or tuned over a limited frequency range when the RECEIVE SELECTOR switch is in TUNE position.

The second section of the receiver consists of a mixer and crystal controlled oscillator, intermediate frequency amplifier, second detector and noise limiter, and a special squelch circuit.

The 10 mc signal received at the grid of the second mixer, V3A, is heterodyned with a 10455 kc signal from the crystal controlled oscillator, V3B. The difference frequency of 455 kc is selected in the plate circuit of V3A and transformer coupled to the control grid of the intermediate frequency amplifier, V4. The gain of this amplifier is also automatically controlled by the AVC system connected to the grid of V4 through the secondary of transformer T1 and 220 K ohm resistor.

The signal is further amplified in V4 and coupled from the plate through transformer T2 to the plate of the detector, V5A, where the audio component is detected. V5A is also used to produce the AVC voltage. The detected signal is coupled to V5B which acts as a series-type noise limiter removing noise pulses which may ride through on the signal. The squelch circuit consisting of a neon lamp, NE-1, silicon diode, CR-1, and associated components is connected so that the audio section of the receiver is cut off and background noise eliminated when no signal is being received. The cut-off level may be varied by use of the squelch control.

The third section of the receiver is a conventional audio amplifier consisting of a twin triode audio voltage amplifier, 12AX7, V6A-V6B followed by a 6AQ5, V7 tetrode power amplifier. When the transceiver is in RECEIVE position only one-half of the 12AX7 is used. The second triode section, V6B, receives the audio signal from the center tap of the volume control. The audio signal is amplified in V6B whose output is RC coupled to the control grid of the power amplifier, V7. The audio signal is further amplified in V7. The plate of V7 is connected to transformer T-3, which performs a dual function. In RECEIVE position this transformer acts as a normal output transformer with its secondary connected to the speaker. In TRANSMIT position, its function is that of a modulation transformer.

CAUTION: Other than adjustment of the receive crystal trimmers, alignment of the EXECUTIVE Model 100 receiver should not be attempted without proper sweep generator and oscilloscope equipment. If receive crystals are added to the EXECUTIVE Model 100 after the unit leaves the factory, the crystal trimmer capacitor connected to the socket where the new crystal is to be installed should be adjusted as follows:

1. RECEIVE SELECTOR set to position where the new crystal is to be installed.

2. SQUELCH CONTROL set fully counterclockwise to click off.

3. VOLUME CONTROL half open.

Both crystal trimmers are adjusted at the factory, consequently will require only minor adjustment to correct the oscillator for reception on the desired crystal controlled channel. Connect the probe of a VTVM to pin 3 on the accessory socket and the meter ground lead to the chassis of the EXECUTIVE Model 100. Set the meter for negative voltage measurement on the 5 volt scale.

Connect the output of a signal generator of known accuracy such as the INTERNATIONAL C-12B Frequency Meter thru the PK-Box to the antenna connector on the EXECUTIVE Model 100. Set the frequency meter to the desired channel and function switch to RF. Depress the PWR switch to On. Using an insulated alignment tool, carefully adjust the crystal trimmer capacitor for maximum AVC voltage as indicated by the VTVM.

TRANSMITTER CIRCUIT DESCRIPTION

The transmitter is a two-stage unit consisting of a crystal controlled oscillator and neutralized tetrode final amplifier. The crystal oscillator is an electron-coupled Colpitts circuit with the crystal oscillating in the grid cathode circuit. The oscillator uses INTERNATIONAL high stability, fundamental type crystals operating at one-half the desired transmitter output frequency. A twelve position switch, TRANSMIT SELECTOR, is provided to select any one of twelve crystals, which may be installed within the unit. A channel 9 crystal is furnished with the unit and installed in one of the twelve crystal sockets.

The plate circuit of the oscillator is tuned to the second harmonic of the crystal frequency by coil L12. The oscillator output is coupled to the grid of final amplifier, V8, through capacitor C70. The plate circuit of V8 is a shunt-fed, pi matching network. Neutralization is accomplished by capacitor C71, and link coil L12, coupled to the cold end of coil L11.

NOTE: Capacitor C68, which is a small plastic trimmer capacitor should not be adjusted, except by a technician with a commercial F.C.C. license, as this adjustment can effect the frequency of the transmitter.

POWER SUPPLY CIRCUIT DESCRIPTION

A three-way power supply is used in this transceiver. It operates as a conventional, full-wave rectifier circuit on all voltage inputs followed by a capacitor input RC filter network. On 6 or 12 volt battery operation, a vibrator circuit is used to provide the necessary AC voltage for the primary circuit of the power transformer.

The transceiver is supplied with a power cord for operation from 115 volts AC, 60 cycles. The unit may be operated either from 6 volts or 12 volts DC by use of the proper power cord assembly which may be pruchased from your dealer. The power supply is equipped with a thermal circuit breaker for protection on AC operation. For protection on 12 volt DC operation a 7.5 ampere fuse is used with the transceiver. Protection on 6 volt DC operation is provided by a 15 ampere fuse which is supplied with the unit. When 12 volt DC operation is desired the 7.5 ampere fuse must be substituted for the 15 ampere fuse.

CAUTION: Due to wiring changes, the Executive Model 50 115 VAC power cord assembly cannot be used with the Model 100. Use power cord assembly (Part #150-174) with the Model 100 for 115 VAC operation. The 6 VDC power cord assembly (Part #150-118) and 12 VDC power cord assembly (Part #150-119) may be used with both models.

Issued 3/21/62

TRANSMIT-RECEIVE RELAY CIRCUIT DESCRIPTION

By including a transmit-receive relay (TR-1) in this transceiver, the many advantages of "push-to-talk" operation and maximum transfer of energy to and from the antenna are afforded the operator at no extra cost. The circuit consists of a half-wave rectifier which receives its AC voltage from a 12 volt secondary winding on the power transformer. The rectifier is followed by an RC filter network whose output is connected in series with one end of the relay coil. The other end of the relay coil is connected through the microphone socket, to the switch in the microphone. The relay is actuated by depressing the microphone switch button. This completes the 12 volt DC relay circuit to ground and the relay performs the following switching functions:

RECEIVE - In this position the relay is not energized and the antenna is connected to the receiver input, B+ voltages are furnished to the receiver section and one side of the speaker is grounded.

TRANSMIT - The relay is energized and the antenna is switched to the transmitter output circuit, B+ voltages are furnished to the oscillator screen and plate circuits as well as V6A. The speaker voice coil is removed from ground and the cathodes of V6A and V9 are grounded.

CRYSTAL FILTER

The crystal filter for the Executive Model 100 transceiver is designed primarily to reduce adjacent channel interference. It consist basically of a transistor Hi frequency IF amplifier. The filtering action takes place in a specially designed crystal filter operating between the transistor Hi IF amplifier and the second converter input.

ACCESSORY RECEPTACLE

This connector, located on the rear panel of the unit, requires a five prong plug which is furnished with the unit. This plug contains a jumper for internal speaker operation and must be in place for the set to function. For external speaker (4 to 6 ohms) operation, remove the jumper and connect the external speaker between terminals 1 and 5 of the plug.

Also available at terminal #3 of this connector is the negative AVC voltage produced by the second detector of the I.F. unit. This voltage may be used to operate an "S" Meter provided the input impedance of the external meter is one megohm or more.

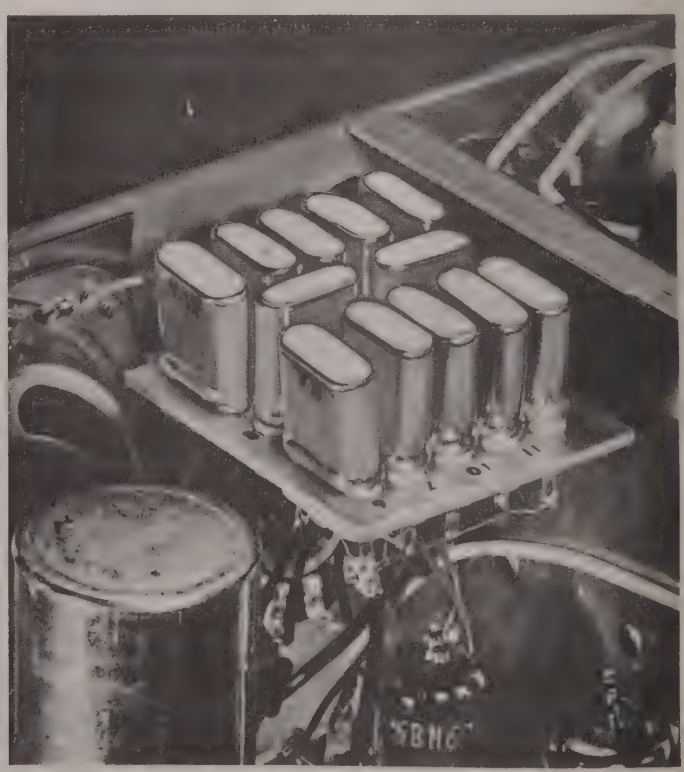
EXECUTIVE MODEL 100
BLOCK DIAGRAM

RECEIVER OSCILLATOR. The EXECUTIVE is delivered without receiver oscillator crystals (left photo) and may be operated to tune all 23 channels of the citizens band with the RECEIVE SELECTOR switch in TUNE position. For fixed tuning in either one or two channels install International type "R" miniature crystals for specific channels (right photo). The two crystals from left to right are controlled by positions #2 and #3 respectively on the RECEIVE SELECTOR switch. Type "R" crystals are listed in Section IV of this manual.



TRANSMITTER OSCILLATOR. The EXECUTIVE is equipped with one channel 9 transmit crystal (left photo). Additional crystals may be installed to permit transmission on either one or more channels. From left to right, the twelve crystals are controlled by positions #1, #2, #3, etc. respectively on the TRANSMIT SELECTOR switch. Transmit crystals are listed in section IV of this manual.

SECTION III
INSTALLATION

The actual placement of the EXECUTIVE unit makes very little if any difference, in its performance. In planning an installation the transceiver should be placed where it will save the most steps. For instance, if the unit is installed in a home to provide communications between the wife at home and her husband in the car, the basement would be a poor location. A more desirable location would be at or near the portion of the house where she spends most of her time, such as in the kitchen, den, or possibly the living room.

FIXED LOCATION INSTALLATION

Operation of the EXECUTIVE from any fixed location such as the home or office will always be best with an outside antenna. A full discussion of antenna selection is given at the end of this section.

MOBILE INSTALLATION

It is possible that the EXECUTIVE, when used in a car or other mobile application, may use a short, base loaded whip, mounted on the rear of the unit. It will not however, prove to be very satisfactory. For best results, a whip, mounted outside the vehicle is required. It may be mounted with a bumper mount on the rear bumper, or may be mounted on a rear fender or cowl, using a ball mount.

The EXECUTIVE itself should be mounted under the dash or in some other practical place in the vehicle. A special mobile mount, designed for the EXECUTIVE is available from INTERNATIONAL which allows the unit to be securely mounted to the car, yet be very easily and quickly removed. Information on this mount is given in the ACCESSORIES section of this manual. Various types of antenna mounts and microphones are also available from INTERNATIONAL.

Installations in cars, planes, boats or other locations near gasoline engines present special problems of their own due to noise created by spark plugs, distributor, voltage regulator and generator. A typical mobile installation is shown in Section IV. Measures which help reduce this noise are discussed at the end of this section.

VIBRATOR CARE IS IMPORTANT

With proper care, the vibrator used in the transceiver power supply for operation of the unit from 6 or 12 volts DC can be extended considerably.

When making a mobile installation the automobile voltage regulator must be adjusted for a maximum generator charging rate of 7.3 volts on 6 volt systems and 14.7 volts on 12 volt systems. Equipment installed in vehicles having the regulator out of adjustment where the generator charging voltage exceeds 7.5 VDC on 6 volt systems or 15 VDC on 12 volt systems shall be considered out-of-warranty.

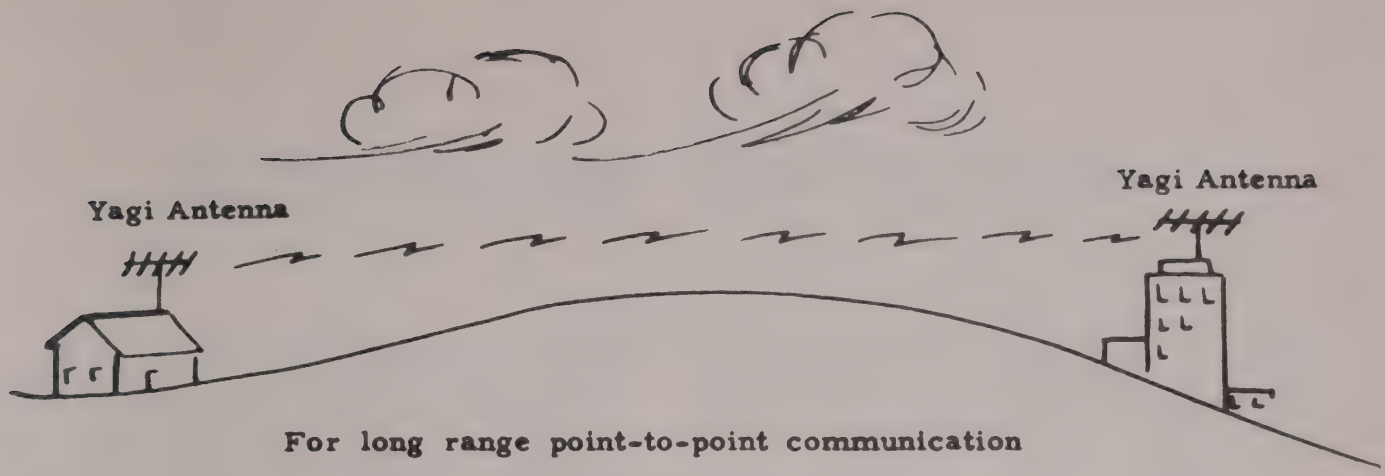
Excessive voltage causes vibrator contact arcing and eventually the contacts will fuse together. When this happens the fuse blows. The replacement of the fuse and vibrator will only be a temproary cure as eventually the same thing will occur again. As an extra safety factor, when the EXECUTIVE is used on 12 VDC the 15 amp fuse should be replaced with a 7.5 amp fuse.

Voltage should be checked at the unit with the engine at fast idle. If it seems as though the battery is fully charged the lights should be turned on for several minutes without the engine running and immediately upon starting the engine the voltage should be noted. If it is excessive the voltage regulator should be adjusted before the equipment is permanently installed. In all cases the voltage must be checked when the generator is charging at maximum.

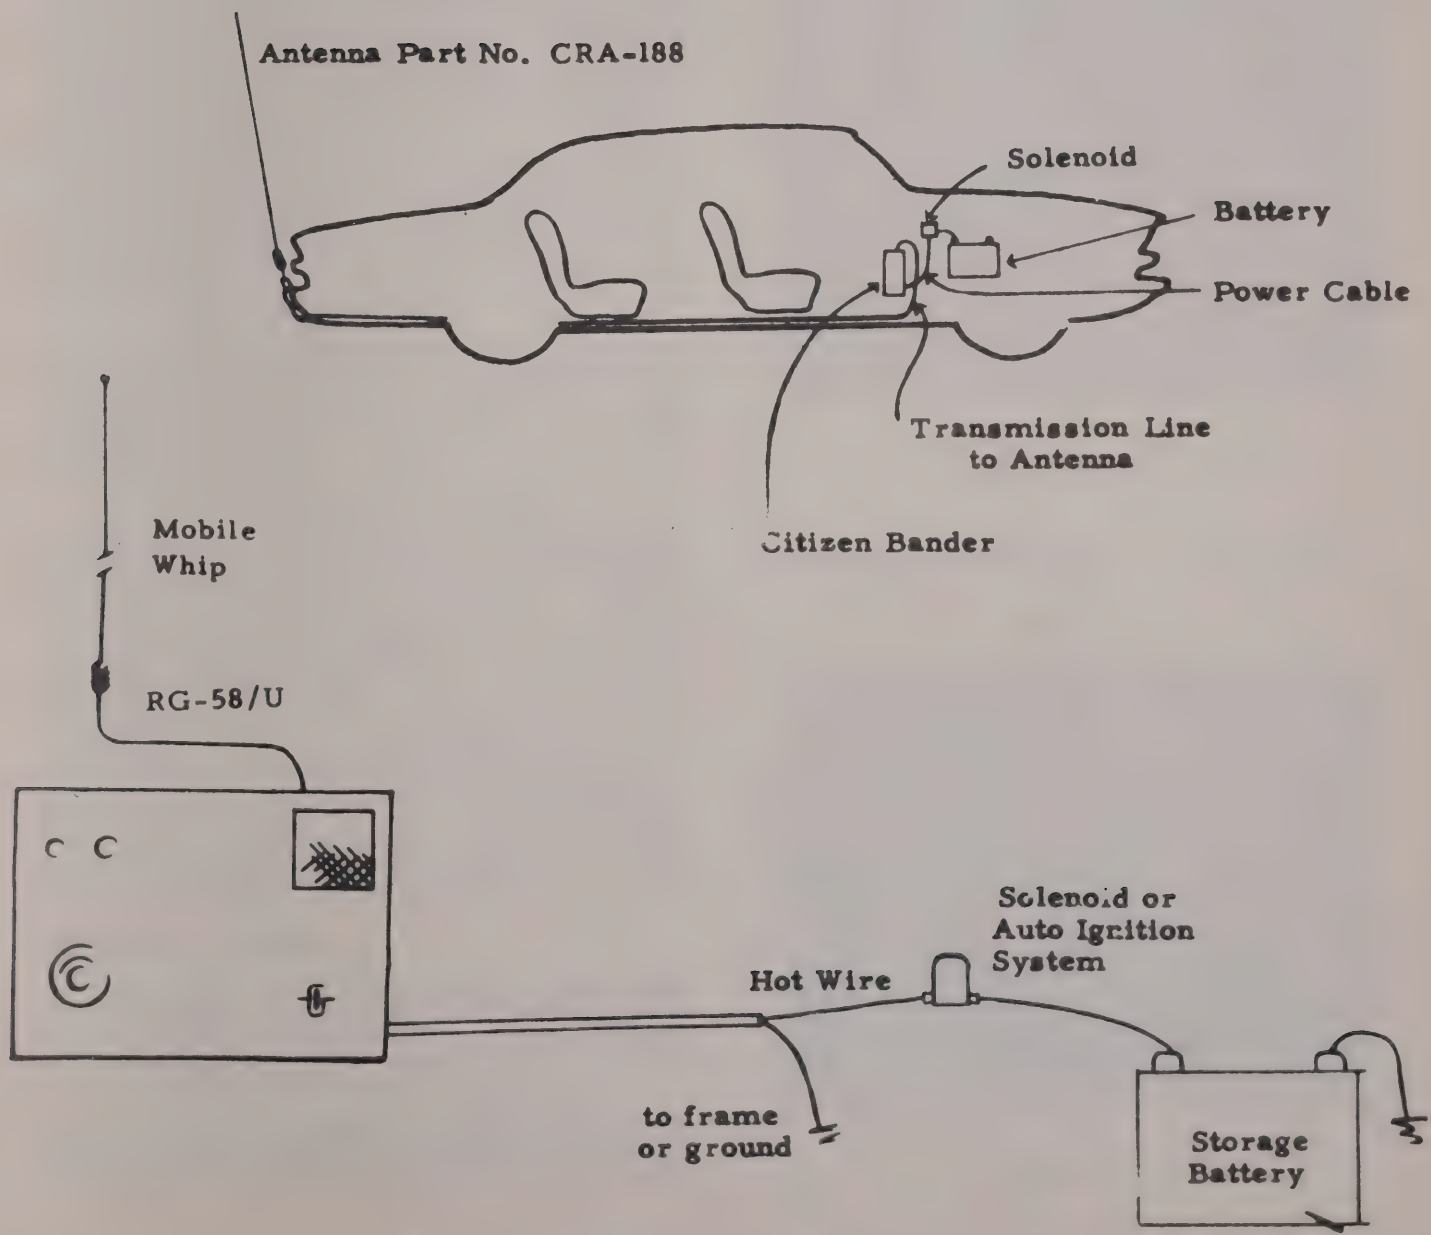
Vibrators have a thirty (30) day warranty, but if you check the voltage properly you will receive many months of trouble-free operation before needing vibrator replacements.

Also of interest is the fact that vibrator contacts will "stick" under a low voltage condition and all users should be advised that under no circumstances should the vehicle be started when the unit is on. Since a tremendous amount of current is drawn from the battery, voltage in some cases will drop to 50% of its normal value during the starting period which is sufficient time for vibrator failure to occur.

INTERNATIONAL will have available soon a test adaptor for use in making these voltage checks and suggest you watch for the announcement. In the meantime use your regular VOM or VTVM for this test. REMEMBER... check the voltage AT THE EQUIPMENT since poor connections or long cable leads will be the cause of a low voltage condition.



For long range point-to-point communication



Typical Mobile Installation

ANTENNAE AND THEIR SELECTION

The most common antennae for citizen use are the Ground Plane and Coaxial for base use and the Vertical Whip for mobile use. The Yagi multi-element beam antenna can be used to great advantage where point-to-point communication is required rather than non-directional coverage from the base station. Any antenna with a directional gain will effectively increase the radiated power of the transmitter as well as the received signal applied to the receiver.

It is best to purchase a good commercially built antenna rather than attempt to construct your own. Good commercial antennae have low SWR (standing wave ratio) which is a merit of the radiation efficiency. With home constructed antennae it is sometimes difficult to effect a good match between the antenna and the transmitter causing considerable power to be lost in the system. An antenna should have an SWR of no more than 2:1.

Some power will be lost in the transmission line and therefore long runs should use the larger RG-8U cable. This cable has a lower loss per foot than the smaller RG-58/U. Both types have a characteristic impedance of 53 ohms. Loss per 100 feet at 27 megacycles is 1 db for RG-8/U and 2 db for RG-58/U. For short runs the RG-58/U cable is more easily handled.

Most of the antennae are available in two grades. The lower priced standard grade will not be as mechanically strong as the commercial grade. Electrically both grades are usually about equal. Where ice loads, wind, and salt air are a factor it will be cheaper in the long run to purchase the better antenna.

For extremely short range communication (less than a mile) the base loaded case whip antenna works very well. With two units using case whips, the signals will become quite weak after a block or two and poor squelch operation will be encountered. The outside antenna is by far the best choice and should be mounted as high as practical and still be within F.C.C. regulations. [Paragraph 19.25(c)]. In brief, the F.C.C. limits antenna height to no more than 20 feet above an existing structure or not to extend above the top of the radiating element on an existing tower. Remember the Yagi type antenna is usually mounted in a horizontal position. This type antenna must be used with another antenna mounted in the same plane. If the Yagi is to be used to communicate with mobile units using a whip antenna, the Yagi should be mounted in a vertical plane. A little thought in antenna installation will greatly improve your coverage.

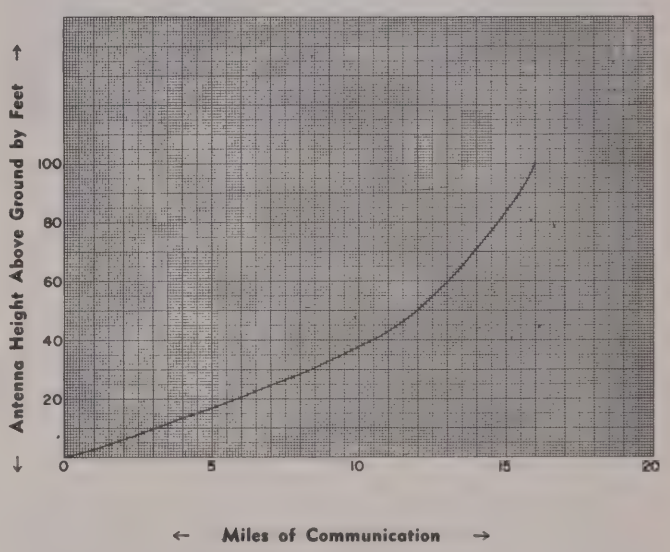
DISTANCE vs ANTENNA

The direct coverage you are able to obtain using Citizen Equipment in the 27 megacycle band will depend a great deal upon the antenna. We shall speak of direct coverage rather than skywave coverage wherein you may communicate 500 to 2000 miles at various times.

The F.C.C. has intended the Citizen use to be for short range communication and all installations should be calculated on this basis. The following charts consider a base station antenna mounted on a mast with the calculated range to a mobile unit using a standard 108" whip. Remember that the antenna may be mounted on an existing structure or mast [reference F.C.C. 19.24(c)].

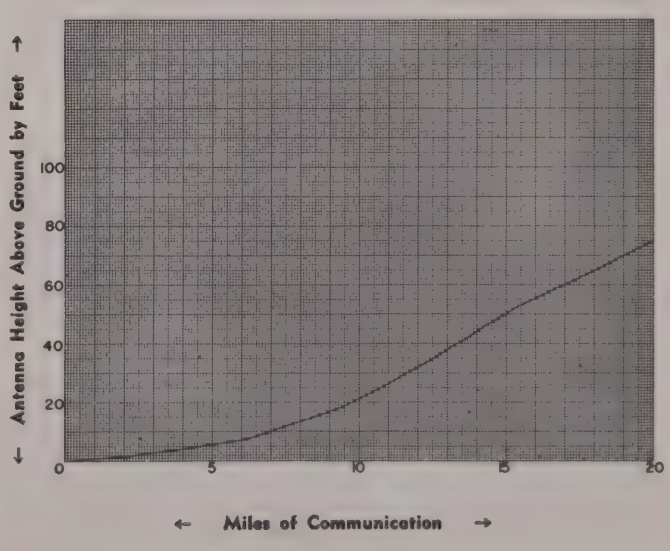
Ground Plane or Coax Antenna For 2 Microvolts at Receiver

Chart #1



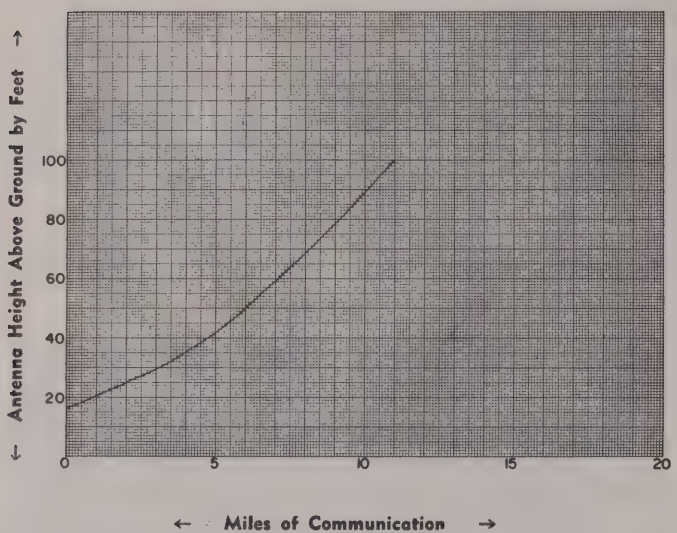
Yagi Antenna Mounted Vertical For 2 Microvolts at Receiver

Chart #2



Ground Plane or Coax Antenna For 15 Microvolts at Receiver

Chart #3



Note how the distance increases with increase height of the antenna for a given installation as in Chart 1. If a direction antenna is used as in Chart 2 you can see how the distance is further increased, however, this reduces the area covered since the Yagi Antenna is quite directional.

Charts 1 and 2 are based on a 2 microvolt signal at the receiver. This signal will not be sufficient for many city areas where high levels of noise exist. Chart 3 considers the coverage for 15 microvolts at the receiver and is more practical for general city use.

When the Citizen frequencies are open to skywave transmission, signals from distant stations will be strong enough to over power weak direct signals. When one is considering communication he should understand that for 100% contact he should base the calculations on 15 microvolts or more.

In mobile communication dead spots will be found at various points as well as locations giving excellent signals. These points should be noted and contacts made from the best possible locations. Vehicle noise and electrical interference will greatly reduce your communicating distance.

ELIMINATE YOUR MOBILE "NOISE GENERATORS"

Now that low cost TWO-WAY radio communication is available to everyone with the opening of the eleven meter band for Citizen use the number of mobile installations will probably exceed the number of base, or control, stations by a factor of 5 to 1 within the near future. It is estimated there are now over 160,000 citizen band mobile installations and approximately 45,000 base, or control, stations in operation. Proper installation and necessary steps towards the elimination of electrical, and mechanical, interference inherent in all motor vehicles is of prime importance if distances of three miles or more are desired to be covered.

For short range coverage the simple installation of a "radio condenser" on the generator and the "interference suppressor" installed in the top of the distributor, or coil, is usually sufficient noise suppression. But when maximum distances of three or more miles must be covered, great pains must be taken and all known means of noise suppression must be used. Different makes and models of vehicles will require different means of noise suppression. Some models only the very simple, others will need the "all out" method.

As there are numerous "generators" of radio interference in every motor vehicle the elimination of one source may not be noticeable as it's noise level may be below one you have not located so the proper way to approach your "noise" problem is by a systematic process of first suppressing all known offenders, namely the generator, voltage regulator, distributor and spark plugs.

We will explain throughout this article what is considered to be the proper vehicle noise suppression methods. The volume of noise you can, or will, tolerate in your receiver will depend upon the amount of suppression applied. Few installations will require the "all out" method and the user must decide when he is satisfied.

The purpose for eliminating your own "noise generators" is the fact that your receiver's automatic volume control (AVC) will react to these random noise pulses the same as though a strong station was tuned-in and will cut the receiver's sensitivity way down which will eliminate the weak stations you normally wish to copy. There's an old saying "if you can't hear them, you can't work them."

Let's start our "noise elimination" with the generator and voltage regulator. The generator is the item that causes the whine as the speed of the motor is increased. It is very easily detected by speeding up the engine and then cutting the ignition off. The instant the switch is turned off ONLY the generator and voltage regulator can cause the noise as all other "noise generators" are eliminated when the switch is off EXCEPT the generator as it is still in operation and is still trying to charge the battery through the voltage regulator. Even though it will operate only a few seconds after the switch is off this is time enough for you to hear the terrific amount of noise it is generating. As the speed of the engine decreases the whine will decrease in unison.

Practically all vehicle manufacturers cable the two leads from the voltage regulator to the generator in a harness with other wires. It is recommended that both of these wires be run in **separate** tinned copper braid. Just disconnect the present wires from the generator and the other end of them at the voltage regulator's "A" and "F" terminals. They can be cut-off where they enter the harness or just taped down out of the way.

A Sprague 48P18 coaxial capacitor, or a similar .5 mfd coaxial capacitor, should be installed directly ON the generator and the lead from the condenser to the battery armature terminal of the generator must be as short as possible. In fact a length of one inch is sometimes too long. A .001 mfd mica capacitor should now be installed from the same battery terminal to the frame of the generator, here again lead length is extremely important and they should be no longer than one-quarter inch. Be sure to remove paint and grease on the generator where the capacitor is bolted as a "good" ground at this point is necessary.

Dress the cable from the coaxial capacitor on the generator against the body of the car. Use speed clips to keep in place or run through presently installed cable clamps. This cable is usually the longest "noise generator" we must suppress and it is preferred to shield this wire in tinned copper braid. The end of the braid must be soldered directly to the coaxial capacitor's body. Be sure to use size #12 copper stranded wire when making-up this new lead. Connect a new cable to the generators' "F" (field) terminal and run this lead in a tinned copper braid shield and dress it along side the battery lead. This new lead may be of size #16 copper stranded wire.

The voltage regulator is next and the "job" from here on is usually easy compared to the one just completed. Remove the cover from the voltage regulator and clean off any paint that may insulate the cover from the frame. Check the mounting screws and be sure the regulator is being grounded directly to the firewall. If necessary remove and clean away any paint so you may secure a "perfect" ground connection.

Use two 48P3 of 48P5 Sprague coaxial capacitors or similar .1 to .5 mfd coaxial capacitors and install at the "A" and "B" terminals of the regulator. The capacitors metal body must be grounded directly to the firewall. This can be easily accomplished by using a piece of cadimun plated metal about 4" x 4" bent to a 90° angle. Drill two holes for the capacitors and two holes to pass sheet metal screws to bolt to the firewall. Attach the capacitors to the angle with screws and nuts and **also** solder. Locate the assembly so the lead from each capacitor to the "A" and "B" regulator terminals are extremely short. Be sure to clean the paint from the firewall so the bracket will make a good solid ground connection. Attach the cable from the generator's "F" terminal to the voltage regulator's "F" terminal. Connect a .002 mfd capacitor and a 4 ohm resistor, in series, from this point to ground. Again, lead length is important and the overall length of the capacitor-resistor combination must be as short as possible. Attach the lead from the generator's armature terminal to the coaxial capacitor connected to the voltage regulator's "A" terminal. The shielding braid on these leads must be grounded to the capacitor bracket or to the firewall by soldering or with the use of washers and sheet metal screws. Attach the "B" battery lead to the coaxial capacitor connected to the "B" terminal of the voltage regulator. This is the lead coming through the firewall and usually goes direct to the battery charging indicator on the vehicles dash panel.

The next superb "noise generators" of them all are the spark plugs. But here we have available to us years of research for only a few dollars. Just go to your local auto supply store and purchase a complete set of AUTO-LITE RESISTOR spark plugs that are direct replacements for your particular brand and model of vehicle. CAUTION: We own no stock in Auto-Lite, but please accept no "substitute" as some **resistor** plugs will actually increase your noise problem. Be patient, if your dealer does not stock your size just ask him to get them for you. When installing the new plugs be sure to have the gap properly set.

After **properly** installing the "recommended" suppression to these trouble makers you should be able to drive comfortably and communicate with stations you never heard before with your engine running. However, in most cases this is only the beginning of the job in order for you to say that you have a good mobile installation.

If you have been checking your "noise elimination" progress as you complete each step we know you will be extremely pleased with your work. But from here on each suppression job will not be very noticeable until you hit the one big joker that's causing a lot of trouble. The little "noise generators" will be obscured by this one and wouldn't have showed up until it was eliminated. All-in-all the little ones can really add up and must be taken care of in due time.

Have your distributor checked to see that the capacitor across the breaker points has the proper capacitance and the points are properly set. If the vehicle has been driven 30,000 to 40,000 miles or more it is recommended that the distributor cap and rotor be replaced. This will usually not only reduce the ignition noise, but also improve the overall performance of the engine. At the same time have the timing checked and properly adjusted.

When purchasing your new AUTO-LITE resistor spark plugs also buy enough 4,000 ohm-per-foot ignition cable to make up a new wiring harness from the distributor to the spark plugs. Be sure that the new terminals (ferrules) are installed whereby they make **good** contact with the center conductor of the new cable. It is preferred that the ferrules be soldered rather than crimped on as there is danger of a poor contact causing another "noise generator" to appear.

Check your ignition wiring by shorting out each plug, in turn, while listening to the receiver. Any reduction in the noise level will usually indicate that the ferrules are not making good contact in the distributor head, or the ferrule and center conductor should be soldered.

Install a 10,000 ohm carbon suppressor in the distributor's center terminal and make up a new lead to run to the coil. Here again be sure the ferrules are soldered and are making a "tight" connection inside the coil and distributor. A new lead is recommended here as any breaks what-so-ever in the ignition system's wiring insulation could be a source of "ignition noise." With very short leads connect a .001 mfd disc ceramic capacitor from the coil's battery terminal to the coil's case.

Bonding braid should now be run from the fire wall, coil, and the distributor to the engine. Use as short a piece of braid as possible in each case. If the ground lead of the battery is attached to the fire wall it should be removed and attached to the starter mounting bolt. The power cable ground lead for your transceiver should also be connected at this same point. Usually the hot and ground leads from the battery go direct to the starter's

enoid which is mounted on the starter and this is a od place to connect the transceiver's power cable. AUTION: Remove the hot cable from the battery before aking connections to the starter as there is danger of the t battery cable getting loose and shorting out the battery even starting a fire.

Connect a short piece of bonding braid across each gine hood hinge. NOTE: The hood will act as a shield help keep the engine noise inside the engine compart-ent and away from your antenna. Next connect a short gth of bonding braid across each trunk lid hinge, front the engine to the frame, exhaust tail pipes to the frame, d a piece of wire braid from the air cleaner to the fire ll. It is very important that we caution you to be sure at you clean away all paint, grease or insulation material en installing the grounding braid as **good,** low resist-ce, ground connections must be made.

Noisy tires should be treated with an anti-static wder, brake shoes grounded to the backup plates with nding braid and static collectors installed inside the nt wheel grease retainer cups. Heat and oil indicator nding units on the engine must be by-passed with .1 to mfd capacitors, again using very short leads. All instru-ent panel gauges and accessories should be by-passed ng .5 mfd capacitors. Heater and defroster motors, ctric windshield wiper motors and any other accessory otors by-passed with a .25 to .5 mfd capacitor. The gaso-e sending unit mounted on the gasoline tank must be -passed with a .1 to .5 mfd capacitor. An inspection te is usually provided in the trunk compartment over e tank.

For the person who desires the "ultimate" in mobile oise elimination" there are available for some vehicles arine and aviation spark plugs that could be used and e complete ignition system shielded by using these plugs d making metal boxes to enclose the distributor and coil, d shielding all wiring associated with the ignition system. having the ignition system **completely** shielded most of the "suppression" can be eliminated and the normal high engine performance will be maintained.

You should set aside a week-end for your "noise elimination" project and have all necessary parts and tools available. You may visit your local two-way radio communications company and secure most of the parts required in kits furnished by some manufacturers of two-way radios. The other parts required are available from radio parts supply and auto parts supply firms.

Lay out your line-of-attack and as each "noise generator" is suppressed it should be noted and checked by listening to the receiver or noting the receiver's "S" meter indication before and after the suppression. This indicates the noise level entering the receiver that is being picked-up by the antenna. To check the noise level entering the receiver by the antenna connecting cable disconnect the cable where it connects to the antenna and short the cable's terminals. If noise is still noticeable it will be necessary to re-route the cable under the vehicle and up through the fire wall to the transceiver. Check the noise level entering the receiver through the power cable by disconnecting the antenna connecting cable at the receiver. All noticeable noise in the receiver is now being picked-up by the power cable and fed to the receiver. This can usually be eliminated by installing a Sprague 48P3 feed-thru coaxial capacitor on the fire wall and the hot battery lead from the transceiver connected through the capacitor to the battery terminal.

We sincerely hope that we have been of some help to you and assure you that when you finish your "noise elimination" project you will consider yourself an "**expert.**" But just as a parting reminder, remember that all of those cars along side of you, up front, behind and the ones passing have not been through the "elimination" process and it will be up to your receiver's built-in noise limiter to cut **their** noises down to a listening level that is bearable.

SECTION IV

ACCESSORIES

MMR-1 MOBILE MOUNT

Available from INTERNATIONAL is a mobile mount designed with the customer's convenience in mind. This accessory permits the transceiver to be installed or removed from the car by simply pulling the unit out, much in the same manner as an ash tray. Details of the mount are shown on another page in this section.

ANTENNAS

Without an efficient antenna, operation of your Executive is not as enjoyable as can be experienced with a well designed antenna system. INTERNATIONAL has available antennas for almost any installation.

EXECUTIVE CRYSTALS

Crystals for the 12 position crystal switch assembly and all other Executive units are also available for transmitting and receiving channels 1 to 23. Frequency and part numbers of these crystals are listed on another page in this section. Price Each $4.75

POWER PLUGS

For our customers who have only one unit and wish to use it in several different locations, INTERNATIONAL offers three different power plugs which will allow the Executive unit to be used anywhere.

6VDC plug	Part No. 150-118	Price Each.....$7.50
12VDC plug	Part No. 150-119	Price Each.....$7.50
115 VAC plug	Part No. 150-174	Price Each.....$7.50
DC plug kit	Part No. 150-191	Price Each.....$3.95
AC plug kit	Part No. 150-192	Price Each.....$3.95

MMR-1
Mobil Mounting Rack

ONLY
$9.95

Complete with necessary mounting hardware

INSTALLATION INSTRUCTIONS

1. Place transceiver up-side-down and remove the four rubber feet. Turn transceiver right side up and spread case at bottom and remove.
2. Place part **A** on top of cabinet and drill four (4) 3/16" holes.
3. Use #8 x ½" screws and bolt part **A** to case. (with screw heads inside case.)
4. Use #8 x ½" screws and bolt strap **C** to part **B.**
5. Position part **B** under dash. Drill two (2) 3/16" holes.
6. Use #8 x 1" screws and bolt part **B** under dash.
7. Fasten part **C** to fire wall or a brace under dash using ¼ x 2" screw.
8. Replace cover on transceiver in reverse to step 1.

Now! In less than 15 minutes installation time you can have the MMR-1 installed. Thereafter you only SLIDE in the transceiver for mobil use and SLIDE out for fix station use.

WIRING POWER PLUG FOR MODEL 100

The 3-way power supply may be operated from any one of three different power sources 115 VAC; 6VDC; or 12VDC. Depending upon voltage to be used, connect the jumper wires to the plug as indicated below. A power cord is included with the kit. If it is desired to connect the plug for battery use, two pieces of #12 or larger battery wire, no longer than three feet, should be used between the plug and battery. DO NOT USE SMALL SIZE WIRE OR LONGER LENGTHS WHEN OPERATING FROM BATTERY AS THIS CAUSES EXCESSIVE VOLTAGE LOSS.

Remove the cover from the power plug by removing the two retainer pins and then separating cover and base. The sketches below are of the connection side of the plug base. Use the #18 buss wire supplied to make jumpers. Where jumpers cross and there is danger of a short, use a length of the insulating sleeving over the wire.

SECTION V

SERVICE AND MAINTENANCE

GENERAL

As is the case with all types of electronic equipment, the EXECUTIVE should be checked periodically by a qualified technician to ensure optimum performance at all times and to correct any condition which might later result in equipment failure due to improper adjustment, tube aging or component failure. Since the EXECUTIVE Series receiver differs somewhat in its design from conventional Citizen Band radio sets, no attempt should be made to service this equipment until the technician has become completely familiar with the basic circuitry and has a thorough understanding of the characteristics of dual conversion equipment.

In general, maintenance can be simplified by seeking a definite symptom of a fault and establishing, by reference to the block and schematic diagrams, a condition or series of conditions which might cause the symptom. This will usually help to localize the source of trouble and eliminate those sections of the equipment which are operating properly.

Many technicians tend to overlook the very simple and more obvious sources of trouble in their service work. This may be brought about by a nontechnical operator's description of a particular fault. For example, a Citizen Band operators complaint of intermittent operation may immediately suggest relay trouble or any number of things to a technician. Yet, upon checking further, the trouble may actually be caused by a defective antenna connector or a loose microphone plug or some other condition completely external to the set. For this reason, always quickly check the entire installation for potential trouble before actually removing the set for maintenance work.

DISASSEMBLY OF THE CABINET

The front and rear panels of the unit are bolted to the chassis, so removal of the cabinet consists of removing the top and sides, which are one complete unit. To remove, turn the unit up-side down and remove four, (4) sheet metal screws which are located inside the four rubber feet. These feet will be removed at the same time. Then turn the unit up right and carefully pull the cabinet sides at the bottom of the unit slightly out and lift the cabinet off.

This will leave the bottom plate still secured to the bottom of the chassis. It is not necessary to remove this plate to service tubes or vibrator. To remove this plate, turn the unit up-side-down and remove the two screws which still remain in the bottom plate, and lift it off.

To re-assemble, simply reverse the procedure outlined above.

TEST EQUIPMENT

A properly equipped Citizen Band service shop will probably have most of the basic test equipment for servicing the INTERNATIONAL EQUIPMENT. Because of the much closer frequency tolerances used on Citizen Band radio equipment, greater precision is required of all alignment generators and frequency measuring equipment. A good stable HF signal generator will be most helpful when alignment of the receiver is necessary. Hewlett-Packard type 606-A signal generator is a good example of the type and quality of instrument which has the inherent stability and accuracy that is desirable for servicing Citizen Band radio equipment. An accurately calibrated attenuator with an auxiliary pad to reduce the generator output to 0.25 microvolts or less is very desirable for absolute receiver sensitivity measurements.

Another invaluable instrument is an RF wattmeter such as the Bird Model 611. This unit with the low power 15 watt element will be most useful for accurately checking transmitter output. The instrument is small and rugged enough for in the field checks on Executives to determine transmitter performance.

For receiver audio recovery measurements, the Heath Model AV-3 Audio Vacuum Tube Voltmeter will provide the necessary accuracy required in this test.

For frequency measurement and modulation percentage checks, the INTERNATIONAL Model C-12B Frequency meter is highly recommended. This versatile instrument specifically designed for use on the Citizen Band Channels, allows the technician to make accurate frequency and modulation checks with the minimum of set up time. The instrument can also be used as an accurate frequency standard for calibration of other equipment on Citizen Band channels.

An adequate source of well filtered low-voltage DC which can be varied over a minimum range of 5 to 15 volts with ample current capacity for good regulation is extremely desirable for service work. Although several automobile batteries can be used with taps at each cell to provide a crude range of adjustment, the upkeep and long range maintenance cost will invariably prove to be more costly than a good battery eliminator type of DC supply. One unit of this type is the Heath Model BE-5. Regulation and filtering are adequate for use directly without the need for batteries.

NOTE

Detailed information and prices on the instruments mentioned above may be obtained by contacting the appropriate manufacturer at the address listed below:
Hewlett-Packard Co., 275 Page Mill Rd., Palo Alto, Calif.
Bird Electronic Corp., 1800 E. 38th St., Cleveland 14, Ohio
International Crystal Manufacturing Co., Inc., 18 N. Lee, Oklahoma City 2, Oklahoma
Heath Company, Benton Harbor, Michigan

PREVENTATIVE MAINTENANCE

Wherever possible, a routine program of preventive maintenance should be set up on all INTERNATIONAL Executive radio installations in order to ensure maximum equipment utilization with the least number of interruptions for service work. The following list has been prepared as a guide to indicate items which should be included in a preventive maintenance program. Unusual environmental or installation conditions may make it necessary to expand or alter this list to meet individual requirements in the field.

GENERAL

Check all plugs, connectors, tubes, vibrators and fasteners for proper seating. Where equipment is subjected to extremely dusty conditions, occasionally remove the set from its case and dust with a clean, dry brush or with a clean, DRY source of compressed air. Clean the relay contacts only by drawing a small strip of ordinary bond letter paper between the contacts while holding gentle pressure on the relay armature. Do not use a file, sandpaper or any abrassive on relay contacts. The contacts are gold-plated and need only occasional cleaning to remove dust or foreign material. Vacuum or brush out any dust in the case before reinstalling the set.

MOBILE INSTALLATIONS

Check the battery connections. These must be clean and tight at all times. Check the battery at frequent intervals for condition and electrolyte level. Add water, as required, to keep the electrolyte at the proper level.

Inspect the power cable for evidence of physical damage. Check the microphone plug, cable and hanger bracket. Check all plugs and connectors for proper seating and security. Inspect the antenna system carefully. Remove the antenna plug from the set and check for continuity between the center contact of the plug and the actual antenna rod with a low range ohmmeter. Straighten or replace any bent or damaged antenna rods.

Check the voltage regulator for proper operation with the engine running. Adjust the regulator, if necessary, to prevent a voltage in excess of 7.5 volts on 6 volt systems or 14.5 volts on 12 volt systems when the generator is operating at its maximum output.

Inspect the distributor and spark plug wiring. Be sure all terminals are clean, bright and fit securely.

BASE STATION INSTALLATIONS

Check the primary line voltage to make certain it is within its normal limits. If the line voltage is subject to very large fluctuations, install a constant voltage transformer of appropriate capacity.

Inspect the microphone plug, cable and hanger bracket for evidence of excessive wear or damage. Check the antenna system, including the mast or tower, guy wires and coaxial cable. Be sure to inspect the ground wire for the mast or tower. All connections at the tower and ground rod should be clean and tight.

MINIMUM PERFORMANCE

The following routine measurements should be made at periodic intervals. If within the range indicated below, the set can be considered in good operating condition.

1. Check the receiver as follows with no signal input. This can be measured with a VTVM and audio output meter. The Volume control should be wide open, Squelch control OFF, Receive Selector in TUNE position and Tuning Dial set at Channel 9. The AVC voltage at terminal #23 on the IF unit should be from -.5 to -.7 and Audio Output across speaker terminals from .3 to .7 VAC. Typical meter readings with a 1 uv 400cps 30% modulated signal are -1.7 to -2.0 volts AVC and 1.8 volts AC or better on the audio output meter.

2. Check the receiver frequency calibration using the C-12B as a signal source on Channels 1, 9 and 22. If the Tuning dial pointer falls within 1/16th of an inch of the Channel numbers marked on the panel, the calibration is satisfactory.

3. Check the transmitter power output with a RF wattmeter. Rated output at standard input voltages of 6.8, 13.6 and 115 volts should be measured. (Normal 2 to 2.5 watts.)

4. If a reflected power meter is available, check the reflected power when transmitting. The reflected power should be almost negligible if the antenna, coax and transmitter are properly matched.

5. Check transmitter output frequency. Frequency should be .005% or better.

TROUBLE LOCALIZATION

To correct any trouble which may occur in the equipment, first try to isolate the section of the set which causes the trouble. In many instances a good visual inspection of the set will clearly indicate where the defective component is located. Reference to the block diagram of circuit functions and the schematic diagrams on the various sections of the receiver, transmitter and power supply, together with the following list of typical symptoms with probable sources of faults will be helpful in servicing the equipment.

When tubes are indicated as being the cause of the trouble, substitute a new tube of the same type for the one suspected of failure. If no improvement is noted, the original may be reinstalled. It should be noted that where tubes are referred to as trouble possibilities, the circuit components immediately associated with that particular tube may also be the source of trouble.

In trouble shooting the equipment, first check the power supply on 6 and 12 volts DC and 115 volts AC. If trouble is not in the power supply, all further checks can be made on 115 volts AC.

Connect a 115 volt power cord to the unit and remove the antenna and connect a dummy load. The dummy load can be made by connecting a #47 pilot lamp across a spare antenna plug and plugging this into the antenna jack of the unit.

VOLTAGE AND RESISTANCE CHARTS.

The E & R Charts gives voltages measured on all tube pins and power pin terminals under both receiving and transmitting conditions. The receiving condition voltages are listed under the column marked "R". The transmitting voltages under column "T". Resistance values are given with power removed and are shown in column marked "Res". The filament voltages are not marked AC or DC, as this will depend on whether or not the unit is being operated on the AC line or on battery input voltage.

All voltage readings are taken with the unit operating from 115 volts AC. Voltages measured when using battery input voltage will differ somewhat from those shown in the chart.

NOTE: R— Voltages measured under no signal condition with VTVOM between tube pin and chassis; Unit operating in RECEIVE position from 115 VAC, VOLUME set at minimum and SQUELCH control off.

ALL READINGS T— Voltage measured with VTVOM between tube pin and chassis; Unit operating in TRANSMIT position into 50 ohm load.

± 10% Res.— Resistance measured with VTVOM between tube pin and chassis; Unit OFF, 115 VAC power plug in place and filter capacitors fully discharged.

POSSIBLE TROUBLE CHART

POSSIBLE POWER SUPPLY TROUBLES

COMPLAINT	POSSIBLE TROUBLE	REMEDY
No B (AC or DC)	Fuse, switch, rectifier	Replace defective parts.
No B (DC)	Vibrator, bad connection on power cable.	Replace vibrator Resolder cable.
B low (DC)	Battery low, power cable to long, vibrator.	Chg. battery, shorten cable, replace vibrator.
B low (AC or DC)	Short in B , bad rectifier, defective power transformer.	Remove short, replace rectifier or transformer.

POSSIBLE TRANSMITTER SECTION TROUBLES

No RF output	Defective V8 or V9	Replace tube (s)
	Open L13 or L14	Replace coil (s)
	Defective transmitter crystal	Replace crystal
	Poor relay contacts	Clean contacts
Low RF output	L11, C78 or C79 improperly adjusted-Defective V8 or V9	Re-adjust coil or capacitors-Replace tube(s)

POSSIBLE RECEIVER SECTION TROUBLES

Dead (no sound)	Defective V1, V2, V3, V4, V5	Replace tube (s)
	Relay contacts dirty	Clean contacts
Low volume	Defective tube as listed above.	Replace defective tube(s)-Align if required.
	Receiver requires alignment	

Issued 3/21/62

RECEIVER ALIGNMENT

Prior to alignment, the Executive should be turned on and allowed to reach normal operation temperature. This will require approximately 15 minutes. Set the Executive operating controls as follows:

VOLUME to ON position

RECEIVE SELECTOR to TUNE position

TUNING DIAL to CHANNEL 9

SQUELCH to OFF - Fully counterclockwise until switch clicks.

NOTE: Disconnect antenna and connect a dummy load to antenna jack. Dummy load may be fabricated from a #47 pilot lamp and a male coaxial connector.

Alignment of the Executive receiver is performed by adjustment of the various stages as follows:

1. The following equipment will be required for the alignment of an executive transceiver with a crystal filter.
   Signal Generator such as H. P. 606A, Clough-Brengle 550 or Equivalent. It is important that the signal generator have a good attenuator and very little leakage signal. A generator such as the Heath LG-1 may be used providing an external pad of approximately 60 db is used and the generator operated on its high ranges.
   Crystal Controlled Frequency Standard: INTERNATIONAL C12-B
   Audio Output Meter such as H. P. -400D, Heath AV-3 or equivalent.
   Vacuum Tube Voltmeter.
   Battery or Battery Eliminator for operation of the unit on 12 VDC.

2. Connect the signal generator through the PK box to the Executive Antenna terminal.

3. Connect the audio meter across the speaker terminals. Use the 3 volt range.

4. Install a Channel 9 receive crystal in position 2 of the Receive Selector Switch.

5. Turn the Executive unit on (use 115 VAC for these steps) and set the Receive Selector to Channel 9.

6. Turn the signal generator to Channel 9 as heard in the receiver. Use 30% modulation on the generator. Turn the C12-B RF Level Control full counterclockwise and selector switch to 9. Key the C12-B and zero beat the signal generator as heard in the Executive receiver.

7. Reduce the Signal Generator output to .3 microvolt and adjust the following coils for peak reading on the audio output meter.

T1---------- top and bottom slugs
T2---------- top and bottom slugs
L2---------- RF Grid
L1---------- Antenna
L4----------RF Plate
L7---------- 1st Mixer Plate
L8---------- 2nd Mixer Plate

8. Set the receiver to TUNE. Set the C12-B on Channel 8 and tune in the C12-B signal on the receiver. Measure the AVC voltage at terminal #23 on the IF board. Set the output RF LEVEL control on the C12-B for 5 volts AVC reading. Leave the RF LEVEL control at this point thru out the rest of the alignment.

9. Set the RECEIVE Selector on the Model 100 for crystal receive on Channel 9. Set the C12-B to channel 9 and carefully zero the signal generator. Apply .3 microvolt on channel 9 from the generator (about 1.5 volts AVC). Adjust the Channel 9 receiver crystal trimmer for maximum reading on the audio meter.

10. Set the C12-B to Channel 8.

11. Coils in the crystal filter are sealed with Dow Compound 881. This seal is rubbery and easily removed with a knife or solder aid point. Remove the seal from L15. Key the C12-B for Channel 8 signal and insert a tuning tool in the slug, turn clockwise (Increase inductance) until the audio meter reading drops to a null. The sharpness of this drop in reading varies and depends somewhat on the input signal from the generator. Now turn the slug counterclockwise until the audio reading just reaches its peak from the sharp rise. Rock the slug back and forth to find the point at the top of the sharp increase. Leave the slug at this point.

12. Turn the set off and remove the 115 VAC cord.

13. Using a 12 inch piece of hookup wire and a .01 mfd ceramic capacitor make up a test jumper. Tack solder the .01 capacitor to lug #12 of the power plug on the bottom of the set. Remove the generator plug and insert the other end of the hook-up wire into the center post of the antenna socket.

14. Connect the 12 VDC power cord to the set and apply 12 VDC power. Turn the set on and volume full on. Adjust coil L8 for minimum reading on the audio meter. You will note an increase in the meter on either side of the correct setting. The minimum reading will be between 1.5 and 2.0 volts audio. (Note: this test applies noise pulses far in excess of those encountered in actual use.)

NOTE: To check for proper alignment of coil L8 it is suggested that the following test be made.

(1) Apply excessive noise to the set as described in step 14 of receiver alignment and adjust the slug of coil L8 to the maximum inductance of the coil form.

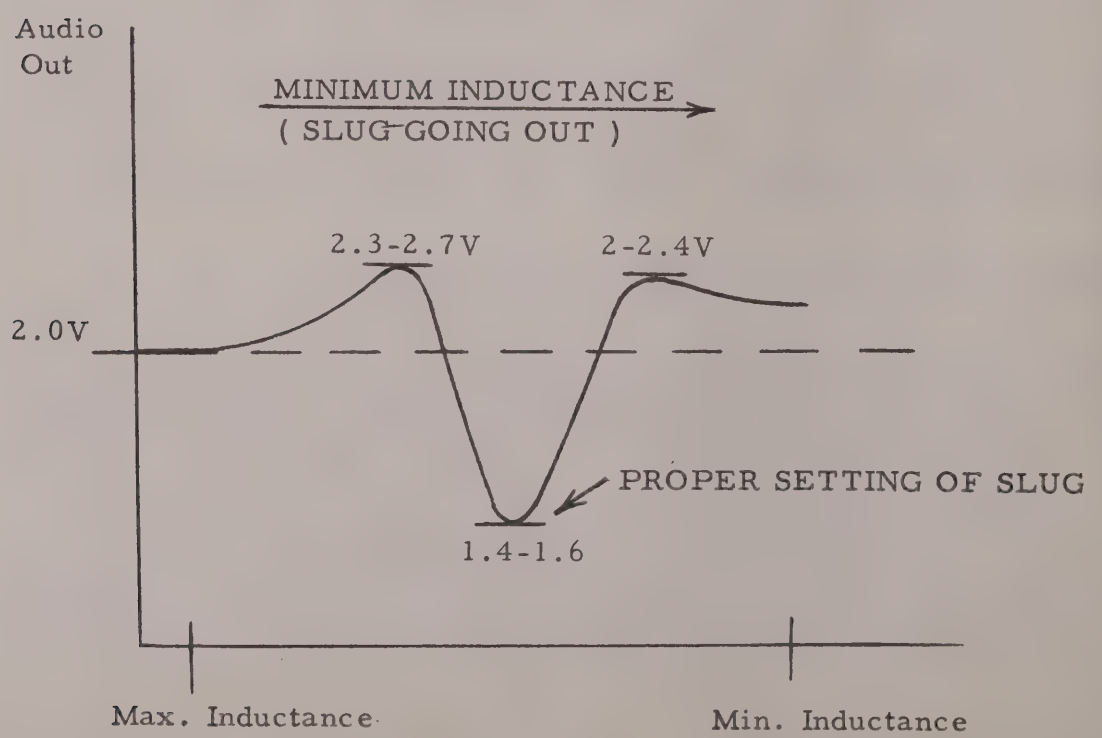
(2) Set the volume control for a meter reading of 2 volts (Use a reliable audio voltmeter such as the Hewlett-Packard 400D).

(3) Slowly rotate the slug of coil L8 out of the form (less inductance), and note the output meter reading as the slug is moved out.

(4) The meter should increase from 2 volts to 2.3-2.7 volts and then drop to a low of 1.4-1.6 volts; after this dip in the meter reading it will start to increase again to a value of 2-2.4 volts.

(5) Note that these readings are taken as the slug is moved from the maximum inductance to minimum inductance. Fig. 1 is a curve of output meter reading vs. slug position for coil L8.

(6) The proper setting of coil L8 is at the bottom of the "valley" or minimum audio output as indicated in Fig. 1.



Noise Clipper

To check for proper operation of the noise clipper circuit;

(1) Remove the noise injection jumper from the antenna receptacle.

(2) Adjust the volume control for a noise level of .03 volts on the output meter. Note that this is not injected noise but the normal noise amplified by the set or "hiss" level.

(3) Reinsert the jumper to the center post of the antenna receptacle to inject vibrator noise. The audio output will increase from .03 volts to .04-.06 volts.

(4) With a .005 mfd capacitor, short out the noise clipper by connecting the capacitor between pin #11 of the IF strip and the junction of resistor R21 and R23 on the IF board. This point can be easily located by noting that there are two 1 meg resistors directly in front of pin #11; the proper junction will be the top end of the second 1 meg resistor which is in series with the 27 K resistor.

(5) The audio output will increase instantly to over 1.5 volts. This is an indication that the noise clipper circuit is functioning properly. The step merely shows the noise present when the clipper circuit is bypassed.

15. Reconnect the generator lead. Set Receive Selector for crystal receive on Channel 9. Set C12-B to 9 and zero signal generator. Apply 1 microvolt on Channel 9 from generator (about 2.2 volts AVC). Reduce the volume control for a reading of 2.5 volts audio on the output meter.

16. While noting audio meter reading set C12-B on 8 and key; then to 10 and key. There should be no more than .5 volt drop in reading when C12-B is keyed (with volume set for 2.5 volts audio on Channel 9). If the channel 9 signal is greatly reduced when 8 or 10 are applied from the C12-B, as previously set up, the filter has not been adjusted properly. A slight readjustment of L15 is required Coil L8 should then be rechecked.

17. In actual operation you should notice considerable improvement of adjacent channel rejection if the crystal filter has been properly installed.

ADJUSTMENT OF TUNABLE FIRST OSCILLATOR

1. Calibration of the receiver tuning dial must be done with a signal generator of known accuracy. If generator accuracy is questionable, it may be calibrated as previously discussed.

2. Set generator on Channel 9 and rotate Executive tuning dial for maximum audio recovery as indicated on output meter. This dial setting should fall within 1/16th of an inch of the panel marking for Channel 9. If the pointer setting is not within this tolerance, adjustment of the 1st converter oscillator will be necessary. Before making any adjustment to the oscillator, it will be necessary to check the receiver tuning spread.

3. Set generator on Channel 1 frequency. Rotate tuning dial towards Channel 1 panel marking. Tune receiver for maximum audio recovery as indicated by the output meter. Note tuning dial pointer position with relation to Channel 1 panel marking.

4. Set generator to Channel 22 frequency. Repaeat procedure of step 3. Note tuning dial pointer position with relation to Channel 22 panel marking. If all three check points are off calibration about the same amount in the same direction, the tuning spread is correct and only the tuning slug in coil L3 needs adjusting at the Channel 9 dial setting to bring the unit back into calibration tolerance.

5. If calibration checks OK at Channel 9 and is off at either the Channel 1 or Channel 22 check points, the tuning spread is incorrect and capacitor C16 must be adjusted.

6. In the first instance described under 4, set generator at Channel 9 frequency and tuning dial pointer at Channel 9 panel mark. Using a small insulated hex tuning tool, slowly adjust the tuning slug in oscillator coil L3 for maximum audio recovery as indicated by the output meter. Check calibration at Channel 1 and Channel 22.

7. In the second instance covered under 9, the following adjustments should be made. Set generator to Channel 9 for frequency. Set receiver tuning dial pointer to Channel 9 panel mark. Using an insulated tuning tool, turn the rotor of capacitor C16 in a clockwise direction until it is fully closed. Rotate rotor of C16 in a counter-clockwise direction for 1 1/2 turns. Adjust tuning slug in oscillator coil L3 for maximum audio recovery as indicated by the output meter. Check calibration at Channel 1 and Channel 22. If calibration is still not within tolerance, alternately adjust capacitor C16 and tuning slug in L3 until calibration falls within the tolerance limits.

8. In instances where the unit has receive crystals installed in the RECEIVE SELECTOR switch assembly crystal sockets, the crystals can be trimmed exactly to the proper channel frequency by their associated capacitors C19 and C20 as follows:

    a. Where the receiver crystal controlled channels are to be used for communication with only one station, such as a base station, "netting" of the receiver using the base station as signal source on the proper channel will produce optimum results.

b. In instances such as covered by a. above, attach an antenna to the Executive antenna jack, set RECEIVE SELECTOR to the proper position. Using the base station signal, adjust the crystal trimmer for maximum AVC voltage as indicated by the VTVM. If there are two crystal control positions being used, repeat the above described adjustment for the second crystal controlled position.

c. Instances where the crystal controlled channels are to be used in communicating with more than one station, set the signal generator up on the proper channel. With the generator in the MCW position, and RF output set a 1 uv, adjust the trimmer capacitor associated with that channel for maximum audio recovery as indicated by the output meter. If both crystal control channels are to be used, repeat the above described adjustment for the second crystal controlled position.

TRANSMITTER ALIGNMENT

The Executive series transmitter alignment can be done with an RF wattmeter, but for a complete check of overall performance the following test equipment will be required.

a. RF wattmeter - Bird 611 or equivalent.
b. Frequency meter with an accuracy of at least .0025% - INTERNATIONAL C-12B or equivalent.

1. Connect an RF wattmeter to the antenna jack on the fack of the Executive.
2. Turn the set on and allow 15 minutes for the unit to reach normal operating temperature.
3. When several different crystals will be used in the transmitter, select one whose frequency is approximately half-way in between the others.
4. Key the transmitter by depressing the microphone press-to-talk switch.
5. Adjust final amplifier tuning capacitor C78 and loading capacitor C79 alternately for maximum output as indicated by the wattmeter.
6. With the volume control set at the one-half open position, and talking within normal distance from the microphone, adjust oscillator plate coil for maximum upward deflection as indicated on the wattmeter.
7. Depress the press-to-talk switch several times and note whether or not the oscillator starts immediately each time the switch is depressed.

8. The Executive series transmitter has an overall frequency tolerance of .005% or better. UNLESS SUITABLE HIGH-ACCURACY FREQUENCY MEASUREING EQUIPMENT IS AVAILABLE, DO NOT ATTEMPT TO ADJUST THE TRANSMITTER FREQUENCY. A small trimmer capacitor C68, is provided to make minor adjustments in the transmitter frequency.

9. Set TRANSMIT SELECTOR to the Channel previously used for transmitter alignment. Connect C12-B Frequency Meter through the PK-1 pick-up box to the transmitter antenna jack.

10. Set up Frequency Meter for measurement on the channel to be measured. Depress microphone press-to-talk switch and measure the frequency. If the frequency is out of tolerance, adjust trimmer C68 until the transmitter frequency is within tolerance. If this cannot be accomplished within the tuning range of C68, check the other channels in the set. If they can be brought into tolerance with trimmer C68, the crystal can be considered defective and must be replaced. If they cannot be brought into tolerance, possibly either of capacitors C69 or C70 has changed value.

11. Before replacing either of these components, if possible, the crystals in question should be checked in another Executive transmitter. If they still cannot be brought into tolerance, chances are that the crystals are defective and should be replaced. If they can be brought into tolerance in a like unit, capacitors C69 and C70 should be checked and the defective component replaced.

12. Set up C12-B Frequency Meter for modulation check. Key transmitter and talk into microphone at a normal level with a prolonged AHHHH. The Executive Transmit indicator lamp should begin to flicker and modulation percentage should be approximately 95%. This completes the transmitter alignment.

WARRANTY

International Crystal Manufacturing Company warrants the parts and tubes in any International Citizen Transceiver to be free from defects in workmanship and material arising from normal usage. Its obligation under this warranty is limited to replacing any such parts or tubes of the receiver which, after regular installation and under normal usage and service, shall be returned within ninety (90) days from the date of original purchase of the set to the authorized dealer from whom the purchase was made and which shall be found to have been thus defective in accordance with the policies established by International Crystal Manufacturing Company.

The obligation of International Crystal Manufacturing Company is limited to making replacement parts available to the purchaser, and does not include either the making or the furnishing of any labor in connection with the installation of such replacement parts nor does it include responsibility for any transportation expense.

International Crystal Manufacturing Company assumes no liability and shall not be liable in any respect for failure to perform or delay in performing its obligations with respect to the above warranty if such failure or delay results, directly or indirectly, from any preference, priority or allocation order issued by the Government or because of any other act of the Government, or by war, conditions of war, inadequate transportation facilities, conditions of weather, acts of God, strikes, lockouts, Governmental controls, or Internationals reasonable requirements for manufacturing purposes, or any cause beyond its control or occurring without its fault, whether the same kind or not.

CONDITIONS AND EXCLUSIONS

This warranty is expressly in lieu of all other agreements and warranties expressed or implied, and International Crystal does not authorize any person to assume for it the obligations contained in this warranty and neither assumes nor authorized any representative or other person to assume for it any other liability in connection with such International units or parts or tubes thereof.

The warranty herein extends only to the original consumer purchaser and is not assignable or transferable and shall not apply to any transceiver or parts or tubes thereof which have been repaired or replaced by anyone else other than an authorized International dealer, service contractor or distributor, or which have been subject to alteration, misuse, negligence or accident, or to the parts or tubes of any receiver which have had the serial number or name altered, defaced or removed.

International Crystal Manufacturing Company is under no obligation to extend this warranty to any unit for which an International registration card has not been completed and mailed to the Company within fifteen (15) days after date of purchase.

FEDERAL COMMUNICATIONS COMMISSION
Washington 25, D.C.

87048
April 15, 1960

UNAUTHORIZED PRACTICES IN BUSINESS AND CITIZENS RADIO SERVICES

An increasing number of reports have reached the Commission concerning the practice of some suppliers of Business and Citizens Radio Services equipment to advise their customers that such equipment may be operated by them prior to the issuance of a radio station license by the Commission. In some instances, sellers have "assigned" radio station call signs to purchasers in conjunction with the sale of radio apparatus and, in a few such cases, these call signs have been identical with those authorized to be used by the manufacturer or seller of the equipment.

A radio station license is required for the use or operation of a radio station in the Business and Citizens Radio Services by Section 301 of the Communications Act. With the exception of certain low power equipment described in Part 15 of the Commission's Rules, the operation of any radio transmission apparatus by a person other than the one to whom the Commission has issued a radio station license is illegal and may result in the imposition of severe criminal sanctions (one year in prison or $10,000 fine, or both) or in the institution of other enforcement action by the Commission.

Under Section 310 (b) of the Communications Act, the prior consent of the Commission is required for the transfer or assignment of any radio station license or the rights granted thereunder. One who fails to observe this provision by the purported transfer of his operating authority subjects himself to possible license revocation and such other enforcement action as the Commission may consider warranted by the circumstances. The denomination of such unlawful activities as "equipment demonstrations" does not render them less illicit.

This matter is being brought to the attention of manufacturers, distributors and retail vendors of Business and Citizens Radio Service communication equipment in the belief that they share the Commission's conviction that the orderly development of these dynamic special radio services is hampered by the above-described practices and that one who engages in such practices, in addition to the possibility of having drastic enforcement action instituted against him, may be sacrificing for the benefit of an immediate sale the long range good will of a misadvised customer.

It is requested that the foregoing be brought to the attention of the personnel in all organizations concerned in any way with the sale, maintenance or use of Business or Citizens Radio Stations in order that a prompt cessation of unlicensed operation of radio stations in these services may be brought about.

-FCC-

F.C.C. RULES & REGULATIONS

PART 19.72 POSTING OF STATION LICENSE

(b) The current authorization of each citizens radio station operated as a mobile station or operated at temporary locations may be retained in the permanent records of the station and need not be posted; However, an executed Transmitter Identification Card (FCC Form 452-C, Revised) shall be affixed to each transmitter which is operated as a mobile station or is operated at temporary locations, and to the control equipment of each such transmitter in every case where such transmitter is not in view from the location from which the station in controlled.

(c) The following information shall be entered on each Transmitter Identification Card (FCC Form 452-C, Revised) which is used for transmitter or station identification in accordance with the foregoing:

(1) Name of the station licensee;
(2) Station call sign assigned by the Commission (see 19.62);
(3) Exact location or locations of the permanent station records;
(4) Frequency or frequencies upon which the assoicated transmitter is adjusted to operate; and
(5) Signature of the licensee.
